These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall,
South Mimms, Barnet.

F. A. H. SIMMONDS
Medical Director.

SIR,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. BOOTH.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

* * *

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver—otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

Letters to the Editor

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical B Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace any one of us, or our families, might be in like . I hope subscribers to the fund will send an donation to make this Christmas a little less grim. I earnestly ask those who are not show their sympathy for their less fortunate not only by sending Christmas gifts, but by regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent F

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you implication that the true incidence of at the present time is probably much below, and ma no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in and 25 in September, suggesting a continued incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September th were 11 notifications, but only 3 of these are now reg as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases diagnosed. For instance, whereas in June all 6 cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the rem 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stages often difficult if not impossible, and doctors ge have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of dia in a substantial proportion of cases. If such as have been obtained in Leeds are common exper any assessment of the progress of the epidemic on notification figures must be highly fallacious. It however, seem to be a fair assumption that the ep is declining quicker than the notification figures imply.

J. F. WARIN
Leeds. Deputy Medical Officer of Heal

*** Our correspondent presents useful evidence the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, ho that the epidemic has attacked fewer people than number notified. Probably the large majority of of poliomyelitis are not clinically recognisable as and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl H (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under auspices of the Queen's Institute, who are thus equipping themselves for further demands likely to under the National Health Service Act. For years district nurses have had the collaboration of members of the Order of St. John and Red Cross Society, so they

dy possess the experience in dealing with voluntary ers desired by Dr. Harding. For the time being r activities have competed for the services of these bodies, though at no previous time has there been uch opportunity to use them in association with the ict-nursing service.

e district nurses are the only section of the nursing munity who are associated with the health services, istinct from the hospital services. Their position rves to be as widely appreciated by all who are erned with the health of the people as their services y their patients.

C. E. A. BEDWELL
Chairman, Metropolitan Federation of Queen's District Nursing Associations.

don, S.E.24.

R,—Miss Steel (Oct. 4) aptly describes the problem ned by me in my previous letter (Sept. 27) as the an's-land of social medicine, and she seems to agree this territory could well be covered to a considerable nt by voluntary workers. Whether the supervision hese workers is effected through the health visitor r the local authority, or the almoner at the divisional th centre referred to by Miss Sayle, seems to me aterial—a question in fact of availability of onnel.

he chairman of the Nursing Recruitment Committee, ing in the *Times* of Oct. 8, refers to the shortage ealth visitors and to the extension of their duties n the National Health Service Act comes into force 948. It is clear that very careful use of all our ned medical social workers will be essential in the s ahead, if the ever-widening fields of work which be their province are to be properly covered. My is that those voluntary workers who for so many s have satisfactorily filled a gap in our social services be given an opportunity to help cover that part field where specific medicosocial training is not ssary.

don, S.W.10. A. E. B. HARDING.

MENINGITIS LEPTOSPIROSA

R,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent omeningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in mpshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric oughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebro-nal fluid (C.S.F.). These too were in young people o were apparently infected by contact with river ter, though 3 had done nothing more daring than dle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

All my cases, however, have shown several features, ical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which sisted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

Though I have not found nitrogen retention approach-g that seen in the icteric cases, yet blood-urea findings ve always been suggestively close to the upper limits normality for young people; and my figures have en higher than those recorded by Buzzard and Wylie. have seen levels of 50 mg. per 100 ml. and higher in ost of the cases. This examination was, however, ade two and sometimes three days earlier than in e Oxford series. It seems possible that nitrogen tention is a very early feature, and as I have written ewhere,[1] I feel that "this is by far the most important ngle laboratory finding" in the early stages. In inchester it was arranged that Dr. C. H. Wrigley, the onorary pathologist, should estimate the urea content f the C.S.F. whenever pleocytosis with normal chlorides as found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

KENNETH ROBERTSON.

94th (Hamburg) British Military Hospital, B.A.O.R.

REVOLT FROM THE BEDPAN

SIR,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver—otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Ben Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace of any one of us, or our families, might be in like need. I hope subscribers to the fund will send an donation to make this Christmas a little less ble grim. I earnestly ask those who are not subscri show their sympathy for their less fortunate coll not only by sending Christmas gifts, but by b regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you sugge implication that the true incidence of poliomy at the present time is probably much below, and ma no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in Au and 25 in September, suggesting a continued incre incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were only accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September t were 11 notifications, but only 3 of these are now rega as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases b diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the remai 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gene have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of diag in a substantial proportion of cases. If such fig as have been obtained in Leeds are common experie any assessment of the progress of the epidemic l on notification figures must be highly fallacious. It wo however, seem to be a fair assumption that the epide is declining quicker than the notification figures imply

J. F. WARIN
Leeds. Deputy Medical Officer of Hea

*** Our correspondent presents useful evidence t the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, howe that the epidemic has attacked fewer people than number notified. Probably the large majority of c of poliomyelitis are not clinically recognisable as s and therefore escape notification altogether.—ED. L

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl Hard (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the f in which they labour so happily as a "*no-man's-land* The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under t auspices of the Queen's Institute, who are thus alre equipping themselves for further demands likely to under the National Health Service Act. For years t district nurses have had the collaboration of memb of the Order of St. John and Red Cross Society, so th idy possess the experience in dealing with voluntary kers desired by Dr. Harding. For the time being r activities have competed for the services of these bodies, though at no previous time has there been uch opportunity to use them in association with the ict-nursing service.

e district nurses are the only section of the nursing munity who are associated with the health services, istinct from the hospital services. Their position rves to be as widely appreciated by all who are erned with the health of the people as their services y their patients.

C. E. A. BEDWELL
Chairman, Metropolitan Federation of Queen's District Nursing Associations.

ndon, S.E.24.

R,—Miss Steel (Oct. 4) aptly describes the problem ned by me in my previous letter (Sept. 27) as the an's-land of social medicine, and she seems to agree this territory could well be covered to a considerable nt by voluntary workers. Whether the supervision hese workers is effected through the health visitor r the local authority, or the almoner at the divisional h centre referred to by Miss Sayle, seems to me aterial—a question in fact of availability of onnel.

e chairman of the Nursing Recruitment Committee, ing in the *Times* of Oct. 8, refers to the shortage ealth visitors and to the extension of their duties n the National Health Service Act comes into force 948. It is clear that very careful use of all our ned medical social workers will be essential in the s ahead, if the ever-widening fields of work which be their province are to be properly covered. My is that those voluntary workers who for so many s have satisfactorily filled a gap in our social services be given an opportunity to help cover that part e field where specific medicosocial training is not ssary.

ndon, S.W.10. A. E. B. HARDING.

MENINGITIS LEPTOSPIROSA

IR,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent omeningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in mpshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric oughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebronal fluid (C.S.F.). These too were in young people o were apparently infected by contact with river ter, though 3 had done nothing more daring than idle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

All my cases, however, have shown several features, lical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which isted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

Though I have not found nitrogen retention approaching that seen in the icteric cases, yet blood-urea findings e always been suggestively close to the upper limits normality for young people; and my figures have en higher than those recorded by Buzzard and Wylie. have seen levels of 50 mg. per 100 ml. and higher in ost of the cases. This examination was, however, ade two and sometimes three days earlier than in e Oxford series. It seems possible that nitrogen tention is a very early feature, and as I have written sewhere,[1] I feel that "this is by far the most important ngle laboratory finding" in the early stages. In inchester it was arranged that Dr. C. H. Wrigley, the onorary pathologist, should estimate the urea content f the C.S.F. whenever pleocytosis with normal chlorides as found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

KENNETH ROBERTSON.

REVOLT FROM THE BEDPAN

SIR,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall, South Mimms, Barnet.
F. A. H. SIMMONDS
Medical Director.

SIR,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. BOOTH.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

Letters to the Editor

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Ben Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace of any one of us, or our families, might be in like nee . I hope subscribers to the fund will send an donation to make this Christmas a little less bl grim. I earnestly ask those who are not subscri show their sympathy for their less fortunate coll not only by sending Christmas gifts, but by b regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you sugge implication that the true incidence of poliomy at the present time is probably much below, and m no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 10 in Au and 25 in September, suggesting a continued incr incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 50 notifications there were only accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September were 11 notifications, but only 3 of these are now reg as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases b diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the remai 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gen have responded to the appeal to isolate and notify suspicion; *this has inevitably meant* revision of diag in a substantial proportion of cases. If such fig as have been obtained in Leeds are common experi any assessment of the progress of the epidemic b on notification figures must be highly fallacious. It w however, seem to be a fair assumption that the epid is declining quicker than the notification figures imply.

J. F. WARIN
Leeds. Deputy Medical Officer of He

⁂ Our correspondent presents useful evidence t the cases notified have included a rising number which the provisional diagnosis of *poliomyelitis* erroneous. It should not be deduced from this, howe that the epidemic has attacked fewer people than number notified. Probably the large majority of c of poliomyelitis are not clinically recognisable as s and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl Harl (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the fi in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved the health-visitor course for district nurses under the auspices of the Queen's Institute, who are thus already equipping themselves for further demands likely to under the National Health Service Act. For years the district nurses have had the collaboration of members of the Order of St. John and Red Cross Society, so they

dy possess the experience in dealing with voluntary ers desired by Dr. Harding. For the time being r activities have competed for the services of these bodies, though at no previous time has there been uch opportunity to use them in association with the ict-nursing service.

e district nurses are the only section of the nursing munity who are associated with the health services, istinct from the hospital services. Their position rves to be as widely appreciated by all who are erned with the health of the people as their services y their patients.

C. E. A. BEDWELL

Chairman, Metropolitan Federation of Queen's District Nursing Associations.

don, S.E.24.

R,—Miss Steel (Oct. 4) aptly describes the problem ned by me in my previous letter (Sept. 27) as the an's-land of social medicine, and she seems to agree this territory could well be covered to a considerable nt by voluntary workers. Whether the supervision ese workers is effected through the health visitor r the local authority, or the almoner at the divisional h centre referred to by Miss Sayle, seems to me aterial—a question in fact of availability of onnel.

e chairman of the Nursing Recruitment Committee, ng in the *Times* of Oct. 8, refers to the shortage ealth visitors and to the extension of their duties n the National Health Service Act comes into force 948. It is clear that very careful use of all our ed medical social workers will be essential in the s ahead, if the ever-widening fields of work which be their province are to be properly covered. My is that those voluntary workers who for so many s have satisfactorily filled a gap in our social services be given an opportunity to help cover that part e field where specific medicosocial training is not ssary.

don, S.W.10. A. E. B. HARDING.

MENINGITIS LEPTOSPIROSA

R,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent omeningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in mpshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric oughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebro-nal fluid (C.S.F.). These too were in young people o were apparently infected by contact with river ter, though 3 had done nothing more daring than ddle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

ll my cases, however, have shown several features, ical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which sisted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

Though I have not found nitrogen retention approach- that seen in the icteric cases, yet blood-urea findings e always been suggestively close to the upper limits normality for young people; and my figures have en higher than those recorded by Buzzard and Wylie. have seen levels of 50 mg. per 100 ml. and higher in ost of the cases. This examination was, however, ade two and sometimes three days earlier than in e Oxford series. It seems possible that nitrogen tention is a very early feature, and as I have written where,[1] I feel that "this is by far the most important ngle laboratory finding" in the early stages. In inchester it was arranged that Dr. O. H. Wrigley, the onorary pathologist, should estimate the urea content f the C.S.F. whenever pleocytosis with normal chlorides as found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

KENNETH ROBERTSON.

94th (Hamburg) British Military Hospital, B.A.O.R.

REVOLT FROM THE BEDPAN

SIR,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall, South Mimms, Barnet.

F. A. H. SIMMONDS
Medical Director.

SIR,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. BOOTH.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

* * *

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver—otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you su implication that the true incidence of poliom at the present time is probably much below, and no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in A and 25 in September, suggesting a continued inc incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were onl accepted cases, the remaining 26 requiring revisi diagnosis. During the last week of September were 11 notifications, but only 3 of these are now re as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September on of the 15 accepted cases had paralysis, the rema 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gen have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of di in a substantial proportion of cases. If such fi as have been obtained in Leeds are common experi any assessment of the progress of the epidemic on notification figures must be highly fallacious. It however, seem to be a fair assumption that the epid is declining quicker than the notification figures imply.

J. F. WARIN
Leeds. Deputy Medical Officer of He

*** Our correspondent presents useful evidence t the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, howe that the epidemic has attacked fewer people than number notified. Probably the large majority of c of poliomyelitis are not clinically recognisable as s and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl Hard (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the fi in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under the auspices of the Queen's Institute, who are thus alr equipping themselves for further demands likely to ari under the National Health Service Act. For years the district nurses have had the collaboration of members of the Order of St. John and Red Cross Society, so they

dy possess the experience in dealing with voluntary ers desired by Dr. Harding. For the time being r activities have competed for the services of these bodies, though at no previous time has there been uch opportunity to use them in association with the ict-nursing service.

e district nurses are the only section of the nursing munity who are associated with the health services, istinct from the hospital services. Their position rves to be as widely appreciated by all who are erned with the health of the people as their services y their patients.

C. E. A. BEDWELL

Chairman, Metropolitan Federation of Queen's District Nursing Associations.

don, S.E.24.

R,—Miss Steel (Oct. 4) aptly describes the problem ned by me in my previous letter (Sept. 27) as the an's-land of social medicine, and she seems to agree this territory could well be covered to a considerable nt by voluntary workers. Whether the supervision hese workers is effected through the health visitor r the local authority, or the almoner at the divisional h centre referred to by Miss Sayle, seems to me aterial—a question in fact of availability of onnel.

e chairman of the Nursing Recruitment Committee, ing in the *Times* of Oct. 8, refers to the shortage ealth visitors and to the extension of their duties n the National Health Service Act comes into force 948. It is clear that very careful use of all our ed medical social workers will be essential in the s ahead, if the ever-widening fields of work which be their province are to be properly covered. My is that those voluntary workers who for so many s have satisfactorily filled a gap in our social services be given an opportunity to help cover that part he field where specific medicosocial training is not ssary.

don, S.W.10. A. E. B. HARDING.

MENINGITIS LEPTOSPIROSA

R,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent omeningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in pshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric oughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebro- al fluid (C.S.F.). These too were in young people o were apparently infected by contact with river er, though 3 had done nothing more daring than dle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

ll my cases, however, have shown several features, ical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which sisted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

Though I have not found nitrogen retention approach- that seen in the icteric cases, yet blood-urea findings ve always been suggestively close to the upper limits normality for young people; and my figures have en higher than those recorded by Buzzard and Wylie. have seen levels of 50 mg. per 100 ml. and higher in ost of the cases. This examination was, however, ade two and sometimes three days earlier than in e Oxford series. It seems possible that nitrogen tention is a very early feature, and as I have written sewhere,[1] I feel that "this is by far the most important ngle laboratory finding" in the early stages. In inchester it was arranged that Dr. C. H. Wrigley, the onorary pathologist, should estimate the urea content f the C.S.F. whenever pleocytosis with normal chlorides as found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

KENNETH ROBERTSON.

REVOLT FROM THE BEDPAN

SIR,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall, South Mimms, Barnet.

F. A. H. SIMMONDS
Medical Director.

SIR,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. BOOTH.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

[1] Robertson, K. M. *Brit. med. J.* 1946, ii, 810.

* * *

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver—otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

Letters to the Editor

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Ben Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace of any one of us, or our families, might be in like n . I hope subscribers to the fund will send an donation to make this Christmas a little less bl grim. I earnestly ask those who are not subscri show their sympathy for their less fortunate coll not only by sending Christmas gifts, but by b regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you sugg implication that the true incidence of poliomy at the present time is probably much below, and no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in A and 25 in September, suggesting a continued incr incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were on accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September were 11 notifications, but only 3 of these are now reg as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the rema 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gene have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of diag in a substantial proportion of cases. If such fig as have been obtained in Leeds are common experi any assessment of the progress of the epidemic b on notification figures must be highly fallacious. It w however, seem to be a fair assumption that the epid is declining quicker than the notification figures imply.

IR,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent omeningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in npshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric oughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebro-al fluid (C.S.F.). These too were in young people o were apparently infected by contact with river er, though 3 had done nothing more daring than dle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

ll my cases, however, have shown several features, ical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which sisted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

Though I have not found nitrogen retention approach- that seen in the icteric cases, yet blood-urea findings e always been suggestively close to the upper limits normality for young people; and my figures have en higher than those recorded by Buzzard and Wylie. ave seen levels of 50 mg. per 100 ml. and higher in st of the cases. This examination was, however, de two and sometimes three days earlier than in e Oxford series. It seems possible that nitrogen ention is a very early feature, and as I have written ewhere,[1] I feel that "this is by far the most important gle laboratory finding" in the early stages. In inchester it was arranged that Dr. C. H. Wrigley, the norary pathologist, should estimate the urea content the C.S.F. whenever pleocytosis with normal chlorides s found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

REVOLT FROM THE BEDPAN

SIR,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall,
South Mimms, Barnet.

F. A. H. SIMMONDS
Medical Director.

SIR,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. BOOTH.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

* * *

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver—otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace of any one of us, or our families, might be in like

I hope subscribers to the fund will send an donation to make this Christmas a little less grim. I earnestly ask those who are not show their sympathy for their less fortunate not only by sending Christmas gifts, but by regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you sugg implication that the true incidence of poliomy at the present time is probably much below, and no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in and 25 in September, suggesting a continued incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September were 11 notifications, but only 3 of these are now rega as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases diagnosed. For instance, whereas in June all 6 noti cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stages often difficult if not impossible, and doctors gen have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of in a substantial proportion of cases. If such as have been obtained in Leeds are common any assessment of the progress of the epidemic on notification figures must be highly fallacious. It w however, seem to be a fair assumption that the epi is declining quicker than the notification figures imply.

J. F. WARIN
Leeds. Deputy Medical Officer of

*** Our correspondent presents useful evidence the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, h that the epidemic has attacked fewer people than number notified. Probably the large majority of of poliomyelitis are not clinically recognisable as and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under auspices of the Queen's Institute, who are thus equipping themselves for further demands likely to under the National Health Service Act. For years district nurses have had the collaboration of of the Order of St. John and Red Cross Society, so the ly possess the experience in dealing with voluntary ers desired by Dr. Harding. For the time being activities have competed for the services of these odies, though at no previous time has there been ch opportunity to use them in association with the ct-nursing service.

district nurses are the only section of the nursing unity who are associated with the health services, stinct from the hospital services. Their position res to be as widely appreciated by all who are rned with the health of the people as their services their patients.

C. E. A. **BEDWELL**
Chairman, Metropolitan Federation of
Queen's District Nursing Associations.
lon, S.E 24.

,—Miss Steel (Oct. 4) aptly describes the problem ed by me in my previous letter (Sept. 27) as the n's-land of social medicine, and she seems to agree his territory could well be covered to a considerable t by voluntary workers. Whether the supervision se workers is effected through the health visitor the local authority, or the almoner at the divisional centre referred to by Miss Sayle, seems to me terial—a question in fact of availability of nnel.

chairman of the Nursing Recruitment Committee, g in the *Times* of Oct. 8, refers to the shortage alth visitors and to the extension of their duties the National Health Service Act comes into force 48. It is clear that very careful use of all our d medical social workers will be essential in the ahead, if the ever-widening fields of work which e their province are to be properly covered. My s that those voluntary workers who for so many have satisfactorily filled a gap in our social services be given an opportunity to help cover that part field where specific medicosocial training is not sary.

REVOLT FROM THE BEDPAN

Sir,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall,
South Mimms, Barnet.

F. A. H. Simmonds
Medical Director.

Sir,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. **W. G. Booth.**

CONVALESCENT HOMES

Sir,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

* * *

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver —otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then probably has to count extra coins, odd transfer tickets, &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

Letters to the Editor

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Ben Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace *any one of us, or our families,* might be in like n . I hope subscribers to the fund will send an donation to make this Christmas a little less bl grim. I earnestly ask those who are not subscri show their sympathy for their less fortunate co not only by sending Christmas gifts, but by b regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you su implication that the true incidence of poliom at the present time is probably much below, and ma no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in A and 25 in September, suggesting a continued inc incidence. A closer analysis of the figures however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were 3 accepted cases, the remaining 26 requiring revisi diagnosis. During the last week of September were 11 *notifications, but only 3 of* these are now re as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases be diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September only of the 15 *accepted cases had paralysis,* the rema 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gen have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of dia in a substantial proportion of cases. If such fi as have been obtained in Leeds are common experi any assessment of the progress of the epidemic on notification figures must be highly fallacious. It w however, seem to be a fair assumption that the epid is declining quicker than the notification figures imply.

J. F. WARIN

Leeds. Deputy Medical Officer of H

*** Our correspondent presents useful evidence t the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, howe that the epidemic has attacked fewer people than number notified. Probably the large majority of c of poliomyelitis are not clinically recognisable as and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl Hard (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under the auspices of the Queen's Institute, who are thus alre equipping themselves for further demands likely to aris under the National Health Service Act. For years the district nurses have had the collaboration of members of the Order of St. John and Red Cross Society, so they ly possess the experience in dealing with voluntary rs desired by Dr. Harding. For the time being activities have competed for the services of these odies, though at no previous time has there been ich opportunity to use them in association with the ct-nursing service.

district nurses are the only section of the nursing unity who are associated with the health services, stinct from the hospital services. Their position res to be as widely appreciated by all who are rned with the health of the people as their services their patients.

C. E. A. BEDWELL
Chairman, Metropolitan Federation of Queen's District Nursing Associations.

lon, S.E.24.

,—Miss Steel (Oct. 4) aptly describes the problem ed by me in my previous letter (Sept. 27) as the n's-land of social medicine, and she seems to agree his territory could well be covered to a considerable t by voluntary workers. Whether the supervision se workers is effected through the health visitor the local authority, or the almoner at the divisional centre referred to by Miss Sayle, seems to me terial—a question in fact of availability of nnel.

chairman of the Nursing Recruitment Committee, g in the *Times* of Oct. 8, refers to the shortage alth visitors and to the extension of their duties the National Health Service Act comes into force 48. It is clear that very careful use of all our d medical social workers will be essential in the ahead, if the ever-widening fields of work which e their province are to be properly covered. My is that those voluntary workers who for so many have satisfactorily filled a gap in our social services be given an opportunity to help cover that part e field where specific medicosocial training is not sary.

don, S.W.10. **A. E. B. HARDING.**

MENINGITIS LEPTOSPIROSA

,—In stressing the importance of anicteric Weil's se, particularly that form presenting as an innocent meningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) recorded cases almost identical with others seen in pshire during the past ten years.

ave now had the good fortune to see some 40 cases oved Weil's disease; about half remained anicteric ghout, and over a dozen of these have presented ses of meningitis showing pleocytosis in the cerebro- d fluid (C.S.F.). These too were in young people were apparently infected by contact with river r, though 3 had done nothing more daring than le. One, an A.T.S. girl of 30, had had no such sure, but her billet was shown to be rat-infested.

l my cases, however, have shown several features, al and laboratory, which seem to have been lacking e Oxford series; and it was these very features h directed attention to the correct diagnosis. All ed muscle tenderness of varying degree which sted until convalescence had been established. I come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ient when going through the infective-hepatitis ls to squeeze each patient's biceps.

ough I have not found nitrogen retention approach- hat seen in the icteric cases, yet blood-urea findings always been suggestively close to the upper limits ormality for young people; and my figures have higher than those recorded by Buzzard and Wylie. ve seen levels of 50 mg. per 100 ml. and higher in t of the cases. This examination was, however, e two and sometimes three days earlier than in Oxford series. It seems possible that nitrogen ntion is a very early feature, and as I have written where,[1] I feel that "this is by far the most important le laboratory finding" in the early stages. In chester it was arranged that Dr. C. H. Wrigley, the orary pathologist, should estimate the urea content he C.S.F. whenever pleocytosis with normal chlorides found; this led to a correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

KENNETH ROBERTSON.

Bus-drivers in New York have an incredible job, for there are no conductors. The two doors at the entrance and exit are opened by the driver pressing a button. The passenger gets on at the driver's end and drops a nickel or a dime into a machine rather like a coffee-grinder. If he intends to transfer to another bus, or return before 4 P.M., he gets a ticket from the driver —otherwise no tickets are needed, for there is only one fare whatever the distance. When all have paid their fares, the driver closes the doors, puts his foot down hard, and off you go. Fluid flywheels make for smooth starting. As the bus proceeds the driver turns a handle and starts the coffee-grinder, which churns up and counts the money. The driver picks the coins out at the bottom of the churn and stacks them in a rack, so he can give change to those foolish enough to need it. He then *probably has to count extra coins, odd transfer tickets,* &c., and make an entry in his log. At the next stop he calls the name of the street, opens the doors, watches the new passengers deposit their coins, issues tickets, closes the doors, watches the traffic and the traffic lights, and starts off again. It really is an amazing act. It seems remarkable that so much should be put on the shoulders of one man, but they tell me he is well paid for it. I missed the humour and courtesy of the London bus conductor, but one cannot blame the New York driver if he keeps strictly to the job on hand.

* * *

Mr. Raffazzia was my first patient on my first firm, and we took each other very seriously. Ever since then he has haunted the hospital. Indeed, he says St. Malaprop's is his second home. It scarcely seems possible to walk through Outpatients without seeing him brooding in some queue. One careless glance and I am trapped: with gentle sweaty fingers he holds my sleeve and talks . . .

Teetering nervously on one foot I gasp: "I really can't stay—I'm late—I've got a lecture—I must go—they're waiting for me in the ward—I'm due in the theatre." All useless cries. He fixes me with the mild milky stare of cataract, and asks eagerly: "Do you remember that day when Nurse Broadbeam dropped the tray?"

For weeks now he has been pestering me to see his daughter. He's very worried about Lucrezia. She's in love with Enrico, and yet won't marry him—says she'd rather have a weekend at Brighton. "It seems so immoral," laments Mr. Raffazzia, "and I'm sure it would do her good to talk it over with a Lady Doctor." "But I'm not qualified." "Never mind," he goes on remorselessly, "you ought to be."

So the other day I had coffee with Lucrezia. She explained that she didn't mind a bit of fun. But marriage? No! She wasn't going to lose her privacy not for anyone. "But what do you do in your privacy?" I asked unhappily. "Surely you could get used to having a husband around, especially as you love Enrico—why must you always be alone in your room?" For the first time she looked embarrassed. After a moment's hesitation she leant across the table and whispered: "I eat biscuits in bed."

* * *

He had been telling me about the model jet-plane. Now he looked at the rusty automatic machine and went into his state of abstraction. At last he came out of it. "Grandpa," said he, "when you were young could you *really* get chocolate out of a thing like that?" "Yes," I replied. "And matches?" "Yes." "For a penny?" "Yes." "Without being registered or having a book?" "Yes." "I *should* have liked it then." "But you wouldn't have had a model jet-plane." "I wouldn't have wanted it," he said; and I felt more hopeful.

Letters to the Editor

A CHRISTMAS APPEAL

SIR,—Christmas comes but once a year, and comes should bring good cheer. I therefore to your readers to help those who have to look to for whatever extra comforts may come their way.

The beneficiaries of the Royal Medical Be Fund are either aged or infirm practitioners, or wives, widows, or children, and but for the grace any one of us, or our families, might be in like need. I hope subscribers to the fund will send an donation to make this Christmas a little less ble grim. I earnestly ask those who are not subscri show their sympathy for their less fortunate co not only by sending Christmas gifts, but by b regular supporters of the fund.

Contributions and subscriptions should be sent secretary of the Royal Medical Benevolent Fund, 1, House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

ALFRED WEBB-JOHNSON
President, Royal Medical Benevolent

INCIDENCE OF POLIOMYELITIS

SIR,—In your note of Sept. 20 (p. 448) you sugg implication that the true incidence of poliom. at the present time is probably much below, and no more than half, the weekly notification figures. recent experience in Leeds supports this view.

The monthly notifications have steadily risen 1 in April to 3 in May, 6 in June, 15 in July, 19 in A and 25 in September, suggesting a continued incr incidence. A closer analysis of the figures s however, that whereas in April, May, and June notifications were true cases, in July, August, September out of 59 notifications there were only accepted cases, the remaining 26 requiring revisio diagnosis. During the last week of September t were 11 notifications, but only 3 of these are now reg as definite cases.

The increasing awareness of poliomyelitis has resulted in a greater number of abortive cases b diagnosed. For instance, whereas in June all 6 no cases showed definite paralysis, in September only of the 15 accepted cases had paralysis, the remai 9 being of the abortive type.

The diagnosis of poliomyelitis in the early stag often difficult if not impossible, and doctors gen have responded to the appeal to isolate and notify suspicion; this has inevitably meant revision of di in a substantial proportion of cases. If such fi as have been obtained in Leeds are common experi any assessment of the progress of the epidemic on notification figures must be highly fallacious. It w however, seem to be a fair assumption that the epid is declining quicker than the notification figures imply.

J. F. WARIN
Leeds. Deputy Medical Officer of H

*** Our correspondent presents useful evidence t the cases notified have included a rising number which the provisional diagnosis of poliomyelitis erroneous. It should not be deduced from this, howe that the epidemic has attacked fewer people than number notified. Probably the large majority of c of poliomyelitis are not clinically recognisable as s and therefore escape notification altogether.—ED. L.

SOCIAL MEDICINE

SIR,—It is remarkable that Dr. Beryl Harl (Sept. 27) does not appear to know the fine work of district nurses, and Miss Steel (Oct. 4) refers to the f in which they labour so happily as a "no-man's-land. The district nurse is par excellence the family doct coadjutor. The Ministry of Health have approved health-visitor course for district nurses under auspices of the Queen's Institute, who are thus already equipping themselves for further demands likely to aris under the National Health Service Act. For years the district nurses have had the collaboration of members of the Order of St. John and Red Cross Society, so they dy possess the experience in dealing with voluntary ters desired by Dr. Harding. For the time being r activities have competed for the services of these bodies, though at no previous time has there been uch opportunity to use them in association with the ict-nursing service.

e district nurses are the only section of the nursing munity who are associated with the health services, istinct from the hospital services. Their position rves to be as widely appreciated by all who are erned with the health of the people as their services y their patients.

C. E. A. **Bedwell**
Chairman, Metropolitan Federation of
Queen's District Nursing Associations.

don, S.E.24.

R,—Miss Steel (Oct. 4) aptly describes the problem ned by me in my previous letter (Sept. 27) as the an's-land of social medicine, and she seems to agree this territory could well be covered to a considerable nt by voluntary workers. Whether the supervision ese workers is effected through the health visitor r the local authority, or the almoner at the divisional h centre referred to by Miss Sayle, seems to me aterial—a question in fact of availability of onnel.

e chairman of the Nursing Recruitment Committee, ng in the *Times* of Oct. 8, refers to the shortage ealth visitors and to the extension of their duties n the National Health Service Act comes into force 948. It is clear that very careful use of all our ed medical social workers will be essential in the s ahead, if the ever-widening fields of work which be their province are to be properly covered. My is that those voluntary workers who for so many s have satisfactorily filled a gap in our social services be given an opportunity to help cover that part e field where specific medicosocial training is not ssary.

ndon, S.W.10. A. E. B. **Harding.**

MENINGITIS LEPTOSPIROSA

R,—In stressing the importance of anicteric Weil's ase, particularly that form presenting as an innocent meningitis, Dr. Buzzard and Dr. Wylie (Sept. 20) e recorded cases almost identical with others seen in pshire during the past ten years.

have now had the good fortune to see some 40 cases proved Weil's disease; about half remained anicteric ughout, and over a dozen of these have presented ases of meningitis showing pleocytosis in the cerebro-al fluid (C.S.F.). These too were in young people were apparently infected by contact with river er, though 3 had done nothing more daring than dle. One, an A.T.S. girl of 30, had had no such osure, but her billet was shown to be rat-infested.

ll my cases, however, have shown several features, ical and laboratory, which seem to have been lacking the Oxford series; and it was these very features ich directed attention to the correct diagnosis. All wed muscle tenderness of varying degree which sisted until convalescence had been established. I e come to rely so much on this sign that in searching Weil's disease during this summer it has seemed ficient when going through the infective-hepatitis rds to squeeze each patient's biceps.

hough I have not found nitrogen retention approach- that seen in the icteric cases, yet blood-urea findings e always been suggestively close to the upper limits normality for young people; and my figures have n higher than those recorded by Buzzard and Wylie. ave seen levels of 50 mg. per 100 ml. and higher in st of the cases. This examination was, however, de two and sometimes three days earlier than in Oxford series. It seems possible that nitrogen ention is a very early feature, and as I have written ewhere,[1] I feel that "this is by far the most important gle laboratory finding" in the early stages. In inchester it was arranged that Dr. C. H. Wrigley, the norary pathologist, should estimate the urea content C.S.F. wh [illegible] ocytosis with normal chlorides [illegible] correct diagnosis in several early cases. In no case was there an excess of polymorphs in the C.S.F.; indeed, the cells have been almost entirely lymphocytes, and case 1 from Oxford with 88% polymorphs must be unusual.

During what has surely been the most tempting summer for bathers in a generation I have seen no cases of Weil's disease in Germany, and I have wondered if the same brilliant sunshine which led possible victims into the water also cut short the life of the young leptospira, which is known to dislike direct sunlight. I understand that no cases have been diagnosed in Winchester this summer—an experience unusual in recent years. I recall that the period July 27 to Sept. 13, 1946, during which all the Oxford cases were seen, was characterised by peculiarly British "summer" weather.

Kenneth Robertson.

94th (Hamburg) British Military Hospital, B.A.O.R.

REVOLT FROM THE BEDPAN

Sir,—Stimulated by your advice and encouragement I designed, with the engineer of this hospital, a chair for use in taking patients to the W.C.; it closely resembles that used for eight years in the Central Hospital, Orebro, which is described by Professor Bohmansson and Dr. Malmros in your issue of Oct. 4.

These chairs have now been used for several months, and I can endorse the views of your contributors on their extreme usefulness. The work of the nurses is reduced and a distasteful task almost eliminated from the ward. Patients greatly prefer to be taken to the W.C. in these chairs and to defæcate in decent seclusion and in a comfortable and effective position; and the effort is much less than that involved in the use of the bedpan. Patients with advanced tuberculosis can use the chair with advantage.

The valuable suggestion of your contributors should be widely adopted in hospitals. Most advances in treatment seem to add more work to overburdened staffs; it is refreshing to meet one which diminishes the amount of work to be done and at the same time greatly improves the comfort and welfare of patients.

County Sanatorium, Clare Hall,
South Mimms, Barnet.

F. A. H. **Simmonds**
Medical Director.

Sir,—Having read with interest the article by Professor Bohmansson and Dr. Malmros, I should like to submit what I believe to be an advance on their suggestion. I have devised a bed which is located over a water-closet pan, and can be manipulated by the patient. The bed has a flap which can be raised to make an opening for the water-closet, and the whole bed can be lowered or raised to allow the patient to sit in a normal position during defæcation. The bed can be operated without the presence or assistance of nurses, and it can be used without moving the patient from bed, thus covering the needs of the bulk of the chronic sick in public-assistance institutions. The cost of fitting the water-closet pans would soon be recovered by the saving of labour, and the offensive odour from bedpans would be eliminated.

Drawings for this bed are in the hands of a firm of hospital-bed manufacturers (Messrs. Whitfields), and it is hoped that a prototype will shortly be in operation.

Boston, Lincs. W. G. **Booth.**

CONVALESCENT HOMES

Sir,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

preserves his equanimity, fearful of expressing any disagreement, accepting even the most preposterous nonsense. I would like to see one, invited, let us say, to hear loud bronchial breathing, protesting irritably and vehemently, "No I don't, I'll be d—d if I do." He ought certainly to pass, whatever his performance in general; he would be the right stuff for a good doctor.

CONVALESCENT HOMES

SIR,—As a patient recently returned from a convalescent home, perhaps my experience may guide those trying to bring about improvements. I was taken to the home from a London hospital, and since it was the first time, after a severe major operation, that I had been dressed and out of the hospital ward, I arrived almost in a state of collapse. The front door was opened by a domestic servant who, without greeting, reprimanded me for being late. I had expected to go straight to bed, but the front door having been shut on my son who had brought me, I was asked to follow her upstairs. I looked at the formidable flight with dismay but managed to crawl unaided to the landing, where I had to stand and wait while the maid unpacked my case. Having been shown my bed in a dormitory for ten, I was asked to come downstairs and see the matron. On

entering her office I sat for the first time, and was again asked to explain my lateness. The arrangements for travelling had, in fact, been made by the hospital. After signing a book, I was told a list of rules, from which I discovered that I must rise at 7.30 A.M. and go to bed at 8.30 P.M. Breakfast was at 8.30 A.M. followed by prayers after which we had to return to the dormitory to make our beds. We were not given our post until this was over, and were not allowed to return to the dormitory again till bed-time. I protested that I was not well enough to be up and dressed all those hours, but was told that if patients wanted to rest they could lie on couches in the sitting-room; but there were only three couches for twelve patients, and one could not always expect to have one of them. We took turns in washing up the dishes after meals. No difference in treatment was made for patients arriving in a state of great weakness and those who had been there several weeks. The food was plain but good, though there were no special diets or extra milk for anyone, whatever their complaints. There was no nursing, and we only saw a doctor once, for two minutes, while he signed our papers. Visitors were not allowed in the house but were asked to go to the back-garden gate to wait for their relations; this seemed particularly ironic to me after reading an article on Broadmoor where I gather the prisoners can be seen on visiting days taking tea with their friends under the shady trees in the prison grounds!

---

[1] Robertson, K. M. *Brit. med. J.* 1946, ii, 810.

I stuck it for two weeks and then left to stay with a kindly landlady in another seaside town, but most of the patients were working women who could not afford to do that. It seems that those who can afford to pay for expensive homes are waited on hand and foot, while the poor—who all too soon are coping with heavy housework and queueing—are regimented back into health almost as if they were mentally deficient or delinquent, and too often in an atmosphere of charity.

There was certainly no intention of being cruel or unkind in this home. It was just sheer lack of imagination. The house was pleasant, nicely furnished, and within a few minutes' walk of the sea. The matron, who meant well enough, warned us on the first day that we were expected to settle in happily with no grumbles and no tears, as she would rather have an empty bed than an unhappy patient. It was quite impossible to relax in such an atmosphere, and the more sensitive patients showed signs of strain which never left them during their stay there.

A PATIENT.

THE METRIC SYSTEM IN MEDICINE

SIR,—Mr. Finnemore lays down in his article (Oct. 11) that "All preparations for internal administration should be written for the single dose . . . the number of doses then being stated."

May I point out that, where dangerous drugs are concerned, such practice is illegal in this country? Under the Dangerous Drugs Act the *total* amount of the drug must be clearly prescribed.

London, W.6. G. E. BREEN.

SYMPTOMS FOLLOWING GASTRECTOMY

SIR,—I am more than interested in the recent views on symptoms following partial gastrectomy. Without going into the previous literature I refer more especially to the article of Gilbert and Dunlop in the *British Medical Journal* of Aug. 30, and the article by Barnes, with an accompanying editorial, in your last issue. I suffer from somewhat similar symptoms myself.

These started a fortnight after a partial gastrectomy, during a somewhat stormy convalescence. After taking a glass of milk, in bed of course, I had an immediate sensation of extreme exhaustion and tiredness, with a consciousness of the heart's action. The really salient feature was the feeling of exhaustion. The symptoms lasted about half an hour, and as soon as I was no longer conscious of the heart's action I felt perfectly normal. The pulse-rate rose from about 70 to a little over 90, with an occasional extra-systole. This was over a year ago and since then I have had fairly frequent similar attacks, always with exactly similar onset; first I have a vague sinking feeling in the pit of the stomach; next I am conscious of the heart's action; and then I feeling of extreme exhaustion.

The symptoms may come on after a meal, but seem to cycles; that is to say, one time I would have them alwa breakfast, another time always after tea, and so on. got three or four attacks a week, and then go a week any. They come on immediately after a meal, and convinced that if I lie down or rest half an hour after a I don't get an attack. Once an attack is over I am fit and can do anything, until the next meal.

The nature of the food taken seems to have no i on the attacks. In fact, I got a slight attack imm after taking glucose for the purposes of performing a sugar curve. The curve rose to 200 mg. per 100 ml minutes, was 100 mg. in 70 minutes, and finally fell to in 130 minutes. But, as I say, an attack started 10 minutes of taking the glucose, when my blood-s 181 mg.

I really cannot see that any of the suggested e tions of this condition apply to my own case. add that my age is 60, my blood-pressure is quite and I have no pain or discomfort whatever refe the stomach. The gastrectomy was performed chronic gastric ulcer which had recurred several and which did not respond to medical treatment.

IODINE AND GOITRE

SIR,—In your leading article of May 31 you disc a recent paper of mine.[1] You properly stated "anyone who sets out to 'debunk' some estab method of preventing disease assumes a certain re bility." I have no desire to evade responsibili anything I have written, in that paper or any but I certainly question the use of "established reference to the prophylactic use of iodine.

You gave your readers a good and detailed acc my paper, although you did not agree with me. does not permit a recapitulation of those of my arg that you discussed and rejected. Your readers judge between us on the basis of your summary your remarks, referring to the original paper for actual evidence.

There were, however, a few considerations that did not mention. In the first place, locally prod foods play only a small part in the feeding of the la cities of the U.S.A. Most of the food comes from t same distant sources. If the published data are ev approximately correct, the amount of iodine furnis by the drinking water and by the local produce be very different in such cities as Cleveland (goi and New York (non-goitrous). The leading Contin protagonist of the "iodine-lack" hypothesis, Fellenberg, conceded in 1938[2] that he was unable find a relation between the iodine content of the and the occurrence of goitre in one community. report has been severely neglected by proponents of iodine-lack hypothesis.

Even though it be conceded that this hypoth false, it might still be true that the administrati iodine should have prophylactic value, just as q and mepacine are useful in the prevention of m Unfortunately, the evidence for the value of iodine not satisfactory. You did not mention the fact only two of those who reported beneficial results trolled their observations in any way, nor did you to the two reports[3,4] of an *increase* in the incidence goitre after the use of iodine.

Post hoc, ergo propter hoc is the oldest of the fall The history of goitre is replete with instances of redu in severity, at least as marked as any that have claimed to follow the use of iodine, that were obse without any known change in the intake of iodine without the slightest reason for supposing that t had been any. Two such instances were mentioned the paper under discussion and a reference was given a previous report containing many more.[5]

RESTRICTION OF BOOK IMPORTS

R,—The regulation issued by the Board of Trade the Treasury prohibiting the import of foreign books pt under individual licence is surely a most serious . It has received astonishingly little attention he medical journals or from official medical bodies. , Sir, mentioned it in a leading article on Sept. 27, to my surprise you seem prepared to tolerate it and wait and see how it works out. Surely such a regula- should arouse at once the gravest protests from the fession's representatives. Have you considered what medical scene will be like if we are cut off from ign, especially American, literature, except through intermediation of the extraordinarily clumsy device an individual licence, subject to the kind permission an anonymous official? You have rightly drawn ention to the slow progress of publication of books the inadequate supply of essential textbooks: we more and more dependent on American works to e these gaps: are we to be cut off?

Our literary colleagues have been much quicker in ognising the importance of this regulation. The *nes Literary Supplement* editorial on Sept. 20 described regulation as "an iron curtain quite as effective, in chosen field, as any political embargo imposed by a alitarian state." Professor Gilbert Murray (*Man- ster Guardian*, Oct. 2) regards the measure "with incredulous amazement": "Who or what is responsible for this particularly obscurantist iron curtain?" he asks. "It will," he rightly says, "be deeply resented by all intellectual workers, scientists, scholars, and philosophers, to whom a knowledge of the work done in other countries is a vital necessity." If medical men still regard themselves as intellectual workers, then surely *now* is the time for you, Sir, the editor of an independent journal, and for the presidents of the Royal Colleges and the B.M.A. whom we expect to represent us, to protest on our behalf until this regulation is withdrawn. Mr. Churchill has had to remind us once more that "the price of freedom is eternal vigilance." It must surely be clear to all by now that our representatives have indeed to be vigilant lest bureaucratic regulations—possibly designed for quite other purposes—have a damaging effect on our medical and scientific progress.

⁂ This subject is discussed editorially on p. 585.—ED. L.

CONFUSION OVER A BLOOD COMPOUND?

SIR,—In their article of Oct. 4, Dr. Gordon and Dr. Brown stated that methæmoglobin was not detected in the washed corpuscles but abounded in the serum. It seems likely that methæmalbumin has been mistaken for methæmoglobin. The former pigment is formed exclusively in the plasma as a result of intravascular hæmolysis (of which there is clear evidence in this case), while the latter is found only in the corpuscles. These two pigments are easily confused since their absorption bands are very close together. Methæmoglobinuria is always secondary, the methæmoglobin being derived from oxyhæmoglobin as it passes down the renal tubules.

Grays, Essex. R. N. HERSON.

ANTI-HISTAMINE SUBSTANCES

SIR,—Among the new anti-histamines it seems that 'Neoantergan' (manufactured in this country as pyranisamine maleate—'Anthisan'), the pharmacologically strongest of the group, will be of great practical importance. Whereas the bronchodilator effect of 'Benadryl' in asthma is doubtful, neoantergan has a definite positive action. I do not want to anticipate its exact clinical evaluation which is in progress, but I think one particular effect should be pointed out—namely, that the bronchodilator effect is nearly always coupled with some drowsiness, known also with benadryl. This is most useful in order to suppress *slight* asthmatic attacks at night. I have found it so in 20 patients who otherwise were woken up regularly by their attacks and had to inhale a spasmolytic drug or to fight the attack by other means. The action of the drug extends also into the early morning and has a beneficial influence on the frequent "early morning wheeze." In such cases the ordinary sedative is of no avail, and I feel it right to make known this effect in advance, because it will be useful to practitioners. (The dose is 0·1–0·2 g.—sometimes more—and nausea is experienced as side-symptom by very few patients.)

It may, I think, be expected that the anti-histamines and the new perlingual adrenaline (isopropyladrenaline—'Aleudrine') which is not yet available in this country, will make the symptomatic treatment of bronchial asthma more satisfactory.

London, W.C.1. H. HERXHEIMER.

STERILITY OF THE THERMOMETER

SIR,—The possibility of transfer of poliomyelitis virus from mouth to mouth by the clinical thermometer merits consideration. The efficacy of popular antiseptic solutions such as phenol and the chemically related chloroxylenols, in destroying virus, is at least dubious: it is stated, in fact, that the virus of poliomyelitis can survive in weak solutions of phenol.[1] On the other hand, the oxidising agents, such as hypochlorite and permanganate solutions, are said to destroy virus readily and with ease.

Sterility of the clinical thermometer possesses a special importance in relation to the régime of mass temperature-taking in operation in certain schools—in one of them

entering her office I sat for the first time, and was again asked to explain my lateness. The arrangements for travelling had, in fact, been made by the hospital. After signing a book, I was told a list of rules, from which I discovered that I must rise at 7.30 a.m. and go to bed at 8.30 P.M. Breakfast was at 8.30 A.M. followed by prayers after which we had to return to the dormitory to make our beds. We were not given our post until this was over, and were not allowed to return to the dormitory again till bed-time. I protested that I was not well enough to be up and dressed all those hours, but was told that if patients wanted to rest they could lie on couches in the sitting-room; but there were only three couches for twelve patients, and one could not always expect to have one of them. We took turns in washing up the dishes after meals. No difference in treatment was made for patients arriving in a state of great weakness and those who had been there several weeks. The food was plain but good, though there were no special diets or extra milk for anyone, whatever their complaints. There was no nursing, and we only saw a doctor once, for two minutes, while he signed our papers. Visitors were not allowed in the house but were asked to go to the back-garden gate to wait for their relations; this seemed particularly ironic to me after reading an article on Broadmoor where I gather the prisoners can be seen on visiting days taking tea with their friends under the shady trees in the prison grounds!

I stuck it for two weeks and then left to stay with a kindly landlady in another seaside town, but most of the patients were working women who could not afford to do that. It seems that those who can afford to pay for expensive homes are waited on hand and foot, while the poor—who all too soon are coping with heavy housework and queueing—are regimented back into health almost as if they were mentally deficient or delinquent, and too often in an atmosphere of charity.

There was certainly no intention of being cruel or unkind in this home. It was just sheer lack of imagination. The house was pleasant, nicely furnished, and within a few minutes' walk of the sea. The matron, who meant well enough, warned us on the first day that we were expected to settle in happily with no grumbles and no tears, as she would rather have an empty bed than an unhappy patient. It was quite impossible to relax in such an atmosphere, and the more sensitive patients showed signs of strain which never left them during their stay there.

A PATIENT.

THE METRIC SYSTEM IN MEDICINE

SIR,—Mr. Finnemore lays down in his article (Oct. 11) that "All preparations for internal administration should be written for the single dose . . . the number of doses then being stated."

May I point out that, where dangerous drugs are concerned, such practice is illegal in this country? Under the Dangerous Drugs Act the *total* amount of the drug must be clearly prescribed.

London, W.6. G. E. BREEN.

SYMPTOMS FOLLOWING GASTRECTOMY

SIR,—I am more than interested in the recent views on symptoms following partial gastrectomy. Without going into the previous literature I refer more especially to the article of Gilbert and Dunlop in the *British Medical Journal* of Aug. 30, and the article by Barnes, with an accompanying editorial, in your last issue. I suffer from somewhat similar symptoms myself.

These started a fortnight after a partial gastrectomy, during a somewhat stormy convalescence. After taking a glass of milk, in bed of course, I had an immediate sensation of extreme exhaustion and tiredness, with a consciousness of the heart's action. The really salient feature was the feeling of exhaustion. The symptoms lasted about half an hour, and as soon as I was no longer conscious of the heart's action I felt perfectly normal. The pulse-rate rose from about 70 to a little over 90, with an occasional extra-systole. This was over a year ago and since then I have had fairly frequent similar attacks, always with exactly similar onset; first I have a vague sinking feeling in the pit of the stomach; next I am conscious of the heart's action; and then I feeling of extreme exhaustion.

The symptoms may come on after a meal, but seem cycles; that is to say, one time I would have them alw breakfast, another time always after tea, and so on. get three or four attacks a week, and then go a week any. They come on immediately after a meal, and convinced that if I lie down or rest half an hour after a I don't get an attack. Once an attack is over I am fit and can do anything, until the next meal.

The nature of the food taken seems to have no on the attacks. In fact, I got a slight attack imm after taking glucose for the purposes of performing a sugar curve. The curve rose to 200 mg. per 100 ml. minutes, was 100 mg. in 70 minutes, and finally fell to in 130 minutes. But, as I say, an attack started 10 minutes of taking the glucose, when my blood-s 181 mg.

SYMPTOMS FOLLOWING GASTRECTOMY

SIR,—I am more than interested in the recent views on symptoms following partial gastrectomy. Without going into the previous literature I refer more especially to the article of Gilbert and Dunlop in the *British Medical Journal* of Aug. 30, and the article by Barnes, with an accompanying editorial, in your last issue. I suffer from somewhat similar symptoms myself.

These started a fortnight after a partial gastrectomy, during a somewhat stormy convalescence. After taking a glass of milk, in bed of course, I had an immediate sensation of extreme exhaustion and tiredness, with a consciousness of the heart's action. The really salient feature was the feeling of exhaustion. The symptoms lasted about half an hour, and as soon as I was no longer conscious of the heart's action I felt perfectly normal. The pulse-rate rose from about 70 to a little over 90, with an occasional extra-systole. This was over a year ago and since then I have had fairly frequent similar attacks, always with exactly similar onset; first I have a vague sinking feeling in the pit of the stomach; next I am conscious of the heart's action; and then I feeling of extreme exhaustion.

The symptoms may come on after a meal, but seem cycles; that is to say, one time I would have them al breakfast, another time always after tea, and so on. got three or four attacks a week, and then go a week any. They come on immediately after a meal, and convinced that if I lie down or rest half an hour after I don't get an attack. Once an attack is over I am fit and can do anything, until the next meal.

The nature of the food taken seems to have no on the attacks. In fact, I got a slight attack im after taking glucose for the purposes of performing a sugar curve. The curve rose to 200 mg. per 100 ml. minutes, was 100 mg. in 70 minutes, and finally fell to in 130 minutes. But, as I say, an attack started 10 minutes of taking the glucose, when my blood-s 181 mg.

I really cannot see that any of the suggested e tions of this condition apply to my own case. add that my age is 60, my blood-pressure is quite n and I have no pain or discomfort whatever refe the stomach. The gastrectomy was performed chronic gastric ulcer which had recurred several and which did not respond to medical treatment.

IODINE AND GOITRE

SIR,—In your leading article of May 31 you di a recent paper of mine.[1] You properly stated "anyone who sets out to 'debunk' some estab method of preventing disease assumes a certain bility." I have no desire to evade responsibili anything I have written, in that paper or any but I certainly question the use of "establish reference to the prophylactic use of iodine.

You gave your readers a good and detailed acc my paper, although you did not agree with me. does not permit a recapitulation of those of my arg that you discussed and rejected. Your readers judge between us on the basis of your summary your remarks, referring to the original paper for actual evidence.

There were, however, a few considerations that did not mention. In the first place, locally p foods play only a small part in the feeding of the cities of the U.S.A. Most of the food comes from same distant sources. If the published data are approximately correct, the amount of iodine fur by the drinking water and by the local produce c be very different in such cities as Cleveland (goit and New York (non-goitrous). The leading Contin protagonist of the "iodine-lack" hypothesis, Fellenberg, conceded in 1938[2] that he was unab find a relation between the iodine content of the and the occurrence of goitre in one community. report has been severely neglected by proponents of iodine-lack hypothesis.

Even though it be conceded that this hypoth false, it might still be true that the administrati iodine should have prophylactic value, just as q and mepacine are useful in the prevention of m Unfortunately, the evidence for the value of iod not satisfactory. You did not mention the fact only two of those who reported beneficial results trolled their observations in any way, nor did you to the two reports[3][4] of an *increase* in the inciden goitre after the use of iodine.

Post hoc, ergo propter hoc is the oldest of the fall The history of goitre is replete with instances of redu in severity, at least as marked as any that have claimed to follow the use of iodine, that were ob without any known change in the intake of iodine without the slightest reason for supposing that had been any. Two such instances were mentioned the paper under discussion and a reference was given a previous report containing many more.[5]

RESTRICTION OF BOOK IMPORTS

R,—The regulation issued by the Board of Trade the Treasury prohibiting the import of foreign books pt under individual licence is surely a most serious . It has received astonishingly little attention he medical journals or from official medical bodies. , Sir, mentioned it in a leading article on Sept. 27, to my surprise you seem prepared to tolerate it and ait and see how it works out. Surely such a regula- should arouse at once the gravest protests from the fession's representatives. Have you considered what medical scene will be like if we are cut off from eign, especially American, literature, except through intermediation of the extraordinarily clumsy device an individual licence, subject to the kind permission an anonymous official? You have rightly drawn ention to the slow progress of publication of books the inadequate supply of essential textbooks; we more and more dependent on American works to e these gaps; are we to be cut off?

Our literary colleagues have been much quicker in ognising the importance of this regulation. The *es Literary Supplement* editorial on Sept. 20 described e regulation as "an iron curtain quite as effective, in chosen field, as any political embargo imposed by a talitarian state." Professor Gilbert Murray (*Man- ter Guardian*, Oct. 2) regards the measure "with incredulous amazement": "Who or what is responsible for this particularly obscurantist iron curtain?" he asks. "It will," he rightly says, "be deeply resented by all intellectual workers, scientists, scholars, and philosophers, to whom a knowledge of the work done in other countries is a vital necessity." If medical men still regard themselves as intellectual workers, then surely *now* is the time for you, Sir, the editor of an independent journal, and for the presidents of the Royal Colleges and the B.M.A. whom we expect to represent us, to protest on our behalf until this regulation is withdrawn. Mr. Churchill has had to remind us once more that "the price of freedom is eternal vigilance." It must surely be clear to all by now that our representatives have indeed to be vigilant lest bureaucratic regulations—possibly designed for quite other purposes—have a damaging effect on our medical and scientific progress.

Royal Infirmary, Manchester. M. C. G. ISRAËLS.

CONFUSION OVER A BLOOD COMPOUND?

SIR,—In their article of Oct. 4, Dr. Gordon and Dr. Brown stated that methæmoglobin was not detected in the washed corpuscles but abounded in the serum. It seems likely that methæmalbumin has been mistaken for methæmoglobin. The former pigment is formed exclusively in the plasma as a result of intravascular hæmolysis (of which there is clear evidence in this case), while the latter is found only in the corpuscles. These two pigments are easily confused since their absorption bands are very close together. Methæmoglobinuria is always secondary, the methæmoglobin being derived from oxyhæmoglobin as it passes down the renal tubules.

Grays, Essex. R. N. HERSON.

ANTI-HISTAMINE SUBSTANCES

SIR,—Among the new anti-histamines it seems that 'Neoantergan' (manufactured in this country as pyranisamine maleate—'Anthisan'), the pharmacologically strongest of the group, will be of great practical importance. Whereas the bronchodilator effect of 'Benadryl' in asthma is doubtful, neoantergan has a definite positive action. I do not want to anticipate its exact clinical evaluation which is in progress, but I think one particular effect should be pointed out—namely, that the bronchodilator effect is nearly always coupled with some drowsiness, known also with benadryl. This is most useful in order to suppress *slight* asthmatic attacks at night. I have found it so in 20 patients who otherwise were woken up regularly by their attacks and had to inhale a spasmolytic drug or to fight the attack by other means. The action of the drug extends also into the early morning and has a beneficial influence on the frequent "early morning wheeze." In such cases the ordinary sedative is of no avail, and I feel it right to make known this effect in advance, because it will be useful to practitioners. (The dose is 0·1–0·2 g.—sometimes more—and nausea is experienced as side-symptom by very few patients.)

It may, I think, be expected that the anti-histamines and the new perlingual adrenaline (isopropyladrenaline—'Aleudrine') which is not yet available in this country, will make the symptomatic treatment of bronchial asthma more satisfactory.

London, W.C.1. H. HERXHEIMER.

STERILITY OF THE THERMOMETER

SIR,—The possibility of transfer of poliomyelitis virus from mouth to mouth by the clinical thermometer merits consideration. The efficacy of popular antiseptic solutions such as phenol and the chemically related chloroxylenols, in destroying virus, is at least dubious: it is stated, in fact, that the virus of poliomyelitis can survive in weak solutions of phenol.[1] On the other hand, the oxidising agents, such as hypochlorite and permanganate solutions, are said to destroy virus readily and with ease.

Sterility of the clinical thermometer possesses a special importance in relation to the régime of mass temperature-taking in operation in certain schools—in one of them

entering her office I sat for the first time, and was again asked to explain my lateness. The arrangements for travelling had, in fact, been made by the hospital. After signing a book, I was told a list of rules, from which I discovered that I must rise at 7.30 A.M. and go to bed at 8.30 P.M. Breakfast was at 8.30 A.M. followed by prayers after which we had to return to the dormitory to make our beds. We were not given our post until this was over, and were not allowed to return to the dormitory again till bed-time. I protested that I was not well enough to be up and dressed all those hours, but was told that if patients wanted to rest they could lie on couches in the sitting-room; but there were only three couches for twelve patients, and one could not always expect to have one of them. We took turns in washing up the dishes after meals. No difference in treatment was made for patients arriving in a state of great weakness and those who had been there several weeks. The food was plain but good, though there were no special diets or extra milk for anyone, whatever their complaints. There was no nursing, and we only saw a doctor once, for two minutes, while he signed our papers. Visitors were not allowed in the house but were asked to go to the back-garden gate to wait for their relations; this seemed particularly ironic to me after reading an article on Broadmoor where I gather the prisoners can be seen on visiting days taking tea with their friends under the shady trees in the prison grounds!

I stuck it for two weeks and then left to stay with a kindly landlady in another seaside town, but most of the patients were working women who could not afford to do that. It seems that those who can afford to pay for expensive homes are waited on hand and foot, while the poor—who all too soon are coping with heavy housework and queueing—are regimented back into health almost as if they were mentally deficient or delinquent, and too often in an atmosphere of charity.

There was certainly no intention of being cruel or unkind in this home. It was just sheer lack of imagination. The house was pleasant, nicely furnished, and within a few minutes' walk of the sea. The matron, who meant well enough, warned us on the first day that we were expected to settle in happily with no grumbles and no tears, as she would rather have an empty bed than an unhappy patient. It was quite impossible to relax in such an atmosphere, and the more sensitive patients showed signs of strain which never left them during their stay there.

A PATIENT.

THE METRIC SYSTEM IN MEDICINE

SIR,—Mr. Finnemore lays down in his article (Oct. 11) that "All preparations for internal administration should be written for the single dose . . . the number of doses then being stated."

May I point out that, where dangerous drugs are concerned, such practice is illegal in this country? Under the Dangerous Drugs Act the *total* amount of the drug must be clearly prescribed.

London, W.C. G. E. BREEN.

SYMPTOMS FOLLOWING GASTRECTOMY

SIR,—I am more than interested in the recent views on symptoms following partial gastrectomy. Without going into the previous literature I refer more especially to the article of Gilbert and Dunlop in the *British Medical Journal* of Aug. 30, and the article by Barnes, with an accompanying editorial, in your last issue. I suffer from somewhat similar symptoms myself.

These started a fortnight after a partial gastrectomy, during a somewhat stormy convalescence. After taking a glass of milk, in bed of course, I had an immediate sensation of extreme exhaustion and tiredness, with a consciousness of the heart's action. The really salient feature was the feeling of exhaustion. The symptoms lasted about half an hour, and as soon as I was no longer conscious of the heart's action I felt perfectly normal. The pulse-rate rose from about 70 to a little over 90, with an occasional extra-systole. This was over a year ago and since then I have had fairly frequent similar attacks, always with exactly similar onset; first I have a vague sinking feeling in the pit of the stomach; next
I am conscious of the heart's action; and then I
feeling of extreme exhaustion.

The symptoms may come on after a meal, but seem to
cycles; that is to say, one time I would have them alw

The really salient feature was the feeling of exhaustion. The symptoms lasted about half an hour, and as soon as I was no longer conscious of the heart's action I felt perfectly normal. The pulse-rate rose from about 70 to a little over 90, with an occasional extra-systole. This was over a year ago and since then I have had fairly frequent similar attacks, always with exactly similar onset; first I have a vague sinking feeling in the pit of the stomach; next I am conscious of the heart's action; and then I feeling of extreme exhaustion.

The symptoms may come on after a meal, but seem cycles; that is to say, one time I would have them alw breakfast, another time always after tea, and so on. I got three or four attacks a week, and then go a week any. They come on immediately after a meal, and convinced that if I lie down or rest half an hour after I don't get an attack. Once an attack is over I am fit and can do anything, until the next meal.

The nature of the food taken seems to have no on the attacks. In fact, I got a slight attack imm after taking glucose for the purposes of performing a sugar curve. The curve rose to 200 mg. per 100 ml minutes, was 100 mg. in 70 minutes, and finally fell to in 130 minutes. But, as I say, an attack started 10 minutes of taking the glucose, when my blood-s 181 mg.

I really cannot see that any of the suggested e tions of this condition apply to my own case. add that my age is 60, my blood-pressure is quite and I have no pain or discomfort whatever refe the stomach. The gastrectomy was performed chronic gastric ulcer which had recurred several and which did not respond to medical treatment.

M.

IODINE AND GOITRE

SIR,—In your leading article of May 31 you disc a recent paper of mine.[1] You properly stated "anyone who sets out to 'debunk' some estab method of preventing disease assumes a certain resp bility." I have no desire to evade responsibilit anything I have written, in that paper or any but I certainly question the use of "established reference to the prophylactic use of iodine.

You gave your readers a good and detailed acco my paper, although you did not agree with me. does not permit a recapitulation of those of my argu that you discussed and rejected. Your readers judge between us on the basis of your summary your remarks, referring to the original paper for actual evidence.

There were, however, a few considerations that did not mention. In the first place, locally prod foods play only a small part in the feeding of the cities of the U.S.A. Most of the food comes from same distant sources. If the published data are approximately correct, the amount of iodine furn by the drinking water and by the local produce be very different in such cities as Cleveland (goi and New York (non-goitrous). The leading Conti protagonist of the "iodine-lack" hypothesis, Fellenberg, conceded in 1938 [2] that he was una find a relation between the iodine content of the and the occurrence of goitre in one community. report has been severely neglected by proponents of iodine-lack hypothesis.

Even though it be conceded that this hypoth false, it might still be true that the administrati iodine should have prophylactic value, just as q and mepacine are useful in the prevention of m Unfortunately, the evidence for the value of iod not satisfactory. You did not mention the fact only two of those who reported beneficial results trolled their observations in any way, nor did you to the two reports [3,4] of an *increase* in the inciden goitre after the use of iodine.

Post hoc, ergo propter hoc is the oldest of the fall The history of goitre is replete with instances of redu in severity, at least as marked as any that have claimed to follow the use of iodine, that were ob without any known change in the intake of iodine without the slightest reason for supposing that had been any. Two such instances were mention the paper under discussion and a reference was give a previous report containing many more.[5]

o advise on measures to prevent spread of infection, t this does not mean she will take over the duties of sanitary inspector.

It will also be the duty of the local health authority provide a home nursing service ; and there are great s to be filled here. Many large well-organised district sing associations adjoin small and impoverished ones, some areas have none. At the start most local health horities will need to make full use of existing services, viding financial support, extra equipment, and transt where these are needed. The services must be lt up so that the family doctor can count on getting aid of the district nurse with as little delay as sible. A strong case can be made, Dr. Banks gests, for placing health visiting, home nursing, and trict midwifery all under one superintendent, who keep in close touch with general practitioners in her a and see that their needs are met.

When arranging aftercare for patients discharged from pital, local health authorities will see that the home ditions are suitable for their reception, and that their ilies are given advice on their care and comfort. provision of home helps is not going to be easy, but Banks believes it can be achieved. The chief need a competent enthusiastic organiser who will get to ow the homes in her area and will herself recruit and ervise the home helps.

Ambulance services are an important item : no excuse be made for failure to provide an ambulance for a e of accident or sudden illness. Local health authori s will work out arrangements most suited to their as, some using existing voluntary organisations, ers combining the various hospital ambulance services the big cities and making them available for surnding areas, others coördinating their organisation h the fire-brigade services. This service, perhaps ve all others under the Act, must be efficient.

Finally the development of health centres must be nned, different kinds of centre being tried before any iform type is considered.

Public Health in Scotland

The report of the Department of Health for Scotland[1] the eighteen months between July, 1945, and ecember, 1946, reveals that, of the 552 men who tered the medical schools in October, 1946, 302 had charged their liability to national service ; while of 2 women entrants, 37 had seen service. Shortage of rses is no less acute in Scotland than in England ; though e number of nurses on the State register increased eadily from 14,228 in 1942 to 17,630 in 1946, and spite some increase in recruitment, the gap between mand and supply is still rapidly widening, for in 1946 ere were 7000 more hospital beds than in 1938. As ewhere, the shortage is greatest in sanatoria and ental hospitals where the nursing staff is about 30 % elow requirements.

The number of persons entitled to benefit under ational Health Insurance rose from 2,047,000 in 1938 o 2,270,000 in 1946 ; the cost per head has almost oubled and now stands at £1 1*s*. 3*d*. The rise in the apitation fee paid to doctors—from 9*s*. to 15*s*.—is thus ot as great as the rise in the cost of other services.

The general health of Scotland at the close of the ar was good. In 1945 the death-rate was 13·2 ; while n 1946 the death-rate was 13·1, the birth-rate 20·3—he highest for 20 years—and the infantile mortality-ate 53·8, which is the lowest on record. The maternal ortality-rate—2·2 and also the lowest ever recorded—has allen steadily to less than one-third of what it was in 1930. Since 1941 when stillbirth became registrable in Scotland, the rate has fallen from 40 to 32 per 1000 total births ; and the neonatal mortality-rate has fallen in the same period from 39·9 to 29 9. These two rates must always be taken together, for the distinction between stillbirth and live birth is legal, not biological.

Notifiable diseases in the period covered by the report were low in incidence and lower still in fatality : notifications of diphtheria fell from 15,069 in 1940 to 4988 in 1946 ; measles and whooping-cough are not generally notifiable in Scotland, but mortality from both diseases show the greatest fall of recent years. Appendicitis is another disease in which mortality has fallen ; it is not certain whether this is due to fall in incidence or to fall in fatality-rate ; but there is some evidence that it is due to the latter through the introduction of chemotherapy.

The incidence of tuberculosis causes some uneasiness. The mortality-rate, which by 1938 had fallen to 69 per 100,000 population, rose steadily to 84 in 1941 ; and the rates for the four succeeding years were 82, 83, 82, and 79. On December 31, 1945, the total number of people in Scotland known to be suffering from tuberculosis was 35,116. Notifications during that year totalled 8477 : 5846 pulmonary and 945 non-pulmonary over 15 years of age, and 721 pulmonary and 965 non-pulmonary under 15 years of age. Deaths numbered 3803 : 2932 pulmonary and 871 non-pulmonary.

Venereal disease, which rose steeply on the outbreak of war, started to decline in 1943. New cases recognised at the clinics in 1945 just exceeded 10,000, of which two-thirds were in males ; but cases of syphilis were equally divided between the two sexes. Patients who attended the clinics and were found not to have venereal disease numbered nearly 8000, and of the females about 50 % were found free ; this suggests that the publicity campaign is succeeding.

The important Water (Scotland) Act, 1946, requires that every new house must have an inside water-supply. Though Scotland had more houses inhabited at the end than at the beginning of the war, the position was worse than that in England. Up to the end of 1946 sites had been approved for 205,703 permanent and 31,226 temporary houses ; but only 5879 permanent and 12,556 temporary houses had been completed.

Poliomyelitis and Polioencephalitis

In the week ended Oct. 4 there was a further slight decline in the notifications of poliomyelitis to 402 (from 441) and of polioencephalitis to 27 (from 32). As was to be expected, the decline since the peak figure of 662 notifications of poliomyelitis in the week ended Sept. 6 has been much slower than the rise had been. It seems probable therefore that a relatively high incidence may persist at any rate throughout the rest of this year. If there is a relatively high winter incidence it will be possible to compare the epidemiological behaviour of the disease in summer and in winter. The rise and fall of the notifications for the last eight weeks is depicted in the table below.

Week ended	No. of cases notified		Percentage increase or decrease in poliomyelitis on preceding week
	Poliomyelitis	Polio-encephalitis	
Aug. 16 ..	646	45	+13·5
,, 23 ..	626	50	− 3·1
,, 30 ..	612	45	− 2·2
Sept. 6 ..	662	46	+ 8·1
,, 13 ..	572	42	−13·5
,, 20 ..	571	23	− 0·2
,, 27 ..	442	32	−22·6
Oct. 4 ..	402	27	− 9·05

In the county of London there were 8 more notifications of poliomyelitis (38 from 30) and 2 less of polioencephalitis (3 from 5). So far this year the deaths ascribed to poliomyelitis and polioencephalitis together in London have numbered 36. This compares favourably with the number of deaths ascribed to whooping-cough (68) and to road traffic accidents (247).

Perhaps the most noteworthy decline in notifications of poliomyelitis this week was in the West Riding of Yorkshire, where the figure fell to 18 from 34.

Infectious Disease in England and Wales

WEEK ENDED OCT. 4

Notifications.—Smallpox, 0 ; scarlet fever, 1086 ; whooping-cough, 1086 ; diphtheria, 218 ; paratyphoid, 16 ; typhoid, 12 ; measles (excluding rubella), 1256 ; pneumonia (primary or influenzal), 330 ; cerebrospinal fever, 46 ; poliomyelitis, 402 ; polioencephalitis, 27 ; encephalitis lethargica, 1 ; dysentery, 97 ; puerperal pyrexia, 134 ; ophthalmia neonatorum, 46. No case of cholera, plague, or typhus was notified during the week.

twice daily—where poliomyelitis has made an appearance. The practice, in such circumstances, of a momentary plunge into antiseptic before placing the thermometer in yet another mouth is to be viewed with apprehension. Nor is the danger special to poliomyelitis: in the case of other virus infections that dwell in the mouth—e.g., those of influenza, the common cold, measles, mumps, and herpes—a similar risk may be incurred; while in your columns on July 19 Mr. Green and Dr. Penfold effectively displayed the possibilities of bacterial contamination.

The best plan surely would be to take temperatures in the axilla rather than the mouth.

London, W.1. MICHAEL ALBURY.

STILBAMIDINE IN MULTIPLE MYELOMA

SIR,—Dr. Napier, in his letter of Sept. 27, draws attention to the late facial neuropathy that frequently follows a course of injections of stilbamidine. Many regard this distressing sequela as a contra-indication to the use of the drug in kala-azar, except in antimony-resistant cases. Even in such cases, its use is no longer necessary now that pentamidine has been shown to be quite as effective (if somewhat slower in its action), provided that it be given in a dosage higher than that originally used by the Calcutta workers.

The manufacturers of stilbamidine would, before now, have withdrawn that drug but for the discovery of its limited value in myelomatosis, in which it often effects early relief of intolerable pain and a partial recovery that may be maintained for many months.

It is to be hoped that Dr. Napier's warning regarding the toxicity of stilbamidine will prevent the further use of that compound in kala-azar, but it would be unfortunate were it to dissuade doctors from prescribing it for a still more serious disease, in which it appears pentamidine may be substituted successfully in only a minority of cases.

May & Baker Ltd., Dagenham. ROBERT FORGAN.

A CAUSE OF FAILURE IN SYMPATHECTOMY ?

SIR,—Your leading article on Sept. 27 referred to an investigation carried out by me.[1] In that study the work of Simmons and Sheehan[2] was confirmed. By ulnar-nerve block it was found that no active sympathetic fibres are present in the main nerves of the upper extremity in the early weeks following either cervicothoracic ganglionectomy or preganglionic section (the Telford operation). I further showed that any sympathetic activity which returned later could be temporarily abolished by procaine block of the thoracic portion of the sympathetic chain, without causing a Horner's syndrome or any sensory or motor changes in the extremity. These findings indicate that the return of sympathetic activity in the hand after operation is not due to the activity of undivided sympathetic fibres lying wholly in the 8th cervical and 1st thoracic spinal nerves or to activity in the small ganglia lying in relation to the spinal nerves of the brachial plexus, as suggested by Skoog.[3]

Regeneration is the only explanation of these observations. This has often been demonstrated in the sympathetic chains of cats and dogs, but its acceptance as the explanation of returned sympathetic activity in man has been slow. Admittedly, it is hard to visualise how the fibres find their way back past the barriers imposed at operation, but they have been shown to have an uncanny power of overcoming obstacles in animals. For conclusive proof of regeneration in man I recently dissected at post-mortem examination the sympathetic chains of a patient who had bilateral lumbar and left cervicothoracic ganglionectomy carried out fifteen years ago, the 2nd, 3rd, and 4th lumbar ganglia and the left cervicothoracic and 2nd thoracic ganglia being removed.

At the time of operation the patient, a female then aged 50, suffered from severe attacks of Raynaud's syndrome in the hands and feet. After the cervicothoracic ganglionectomy there was a well-marked Horner's syndrome which persisted till death, and the left hand was warm, pink, and dry. The condition relapsed, however, about a year after operation. The foot also showed a good result for tw and then gradual relapse.

At post mortem the chains were found to be with no gaps in either lumbar or cervicothoracic regi the mid-lumbar zone the cords were slender and cont ganglia, but were connected to the spinal nerves b communicantes. In the cervicothoracic region ganglion was present in the site of the normal cervico ganglion, and there were numerous rami commu from it to the lower spinal nerves of the brachial There was, in fact, little difference between the operat unoperated sides, except that there was scar tissue ro chain on the former. Regeneration had thus taken very completely in this case.

The persistence of the Horner's syndrome has claimed by some to indicate that regeneration d occur, but in my experience it is the ptosis which and not the miosis. The lasting ptosis can be ex by degeneration of the part of the levator pal superioris supplied by the sympathetic, after its d tion; although the nerve supply may grow bac muscle has lost its power of recovery.

Regeneration occurs frequently after sympath but it is usually very incomplete, and there is no that the great majority of suitable cases are perm benefited by sympathectomy.

I wish to express my thanks to Mr. F. R. Brown, of D for kindly supplying details of the operations and of clinical course. H. A. HAXT

Neurovascular Clinic, Manchester Royal Infirmary.

Public Health

The Third Part

THE third part of the National Health Service dealing with the duties of the new local authorities, has given rise to much discussion and misgivings. Dr. A. L. Banks,[1] of the Ministry of H has lately reviewed some of the points raised.

The responsibilities laid on the new authorities at first sight appear to be merely extensions of the disconnected powers of the past; but this, he sho is not so. For example, the sections relating to midwifery service, the care of mothers and yo children, health visiting, home nursing, immunis ambulance services, and health centres are all de to make the local health authority provide, for p in their homes, the sort of care needed to supple the clinical care given by general practitioners hospitals. The midwifery service will prove par larly difficult to organise, and it is now agreed that ideal will be a team in each area under the ge supervision of an obstetric consultant attached to hospital. The teams will consist of domiciliary midwi and of general practitioners with special experience midwifery, together with the appropriate medi officers of the present local-authority maternity servi He noted that in arranging for the general care expectant and nursing mothers, and of children und the age of five, the local health authority must en continuous medical care for both mother and child, it will be necessary to arrange that medical records continuous, extending from infancy into school adult life.

The position of health visitors has caused so uneasiness; they are to "give advice" on the care expectant and nursing mothers, young children, people suffering from illness, and also on meas necessary to prevent the spread of infection. Dr. Banks explained, is not to be interpreted as infringement of the duties of the family doctor; and instanced the case of a household where the mother is a late stage of pregnancy, one of the young children whooping-cough and possibly early bronchopneumo and an elderly somewhat senile relative lurks in background. Here the health visitor, in agreement the general practitioner, will arrange for a home help, advise the mother on the care of the children, and the best way to deal with the aged relative. She mbers of the Association of Industrial Medical Officers. m the time of its formation in 1935, he guided it through early turbulent years characteristic of the develop- nt of any virile society. Moreover, he was responsible the drafting of a new constitution which, only too lly, he will not see in practice. All those engaged in day-to-day work in factories will vouch for his out- nding qualities of friendship, his great wisdom, and sure dance. His capacity for giving a sound opinion in ew words was perhaps unequalled by anyone in the d of industrial medicine in our time. He was largely ponsible for the high degree of collaboration between Factory Department of the Ministry of Labour and tional Service and the industrial medical officer, ollaboration which proved of the greatest benefit h to the department and to industry."

---

[1] Inaugural address to the summer school of the Women Health Officers Association, 1947.

r. S. H. Wilkes, senior chemical inspector in the tory Department, adds: "No-one without medical wledge would presume to discuss Dr. Bridge's work industrial medicine. But that work necessarily uired him to coöperate with colleagues whose qualifica- ns were in fields other than medicine, and his coöpera- n there deserves the highest praise. Harmony ongst a group of specialists in different, but overlap- g, fields can be maintained only by the exercise of sual sympathy, tact, and good-fellowship. Dr. dge possessed those qualities in an unusual degree, that is why he was so successful as a leader of diverse ms. Always ready to give advice and encourage- nt directly, unconsciously, he was also always giving m indirectly by his example of enthusiasm, of zeal, , at the proper times, of restraint."

Births, Marriages, and Deaths

BIRTHS

CTON.—On Oct. 5, at Croydon, the wife of Dr. Hugh Acton, M.B.E.—a daughter.

LARKE.—On Oct. 8, the wife of Dr. E. G. W. Clarke—a daughter.

DAVIES.—On July 20, to Patience Barclay, M.R.C.P., wife of Arthur Davies—a son.

MOORE.—On Oct. 11, at Manchester, the wife of Dr. W. K. S. Moore—a son.

STOKES.—On Oct. 3, in London, the wife of Dr. J. F. Stokes—a son.

MARRIAGES

MITCHELL—LYELL.—On Oct. 7, at Bolton-le-Sands, Robert Imrie Mitchell, M.B.E., lieut.-colonel, R.A.M.C., to Marion Lyell.

THOMAS—ANDERSON.—On Oct. 8, at Northwood, Harold Ernest Thomas, M.B., to Elizabeth Jean Anderson.

DEATHS

BRADBROOKE.—On Oct. 5, at Horsham, Hugh Nash Bradbrooke, M.A., D.M. Oxfd, M.R.C.P., D.P.M.

COBB.—On Oct. 8, William Grahame Cobb, D.S.O., M.B. Edin., aged 69.

KIRK.—On Oct. 9, Charles Joseph Kirk, M.B. Glasg.

SCOTT.—On Oct. 6, in London, Edward Spencer Scott, B.A., M.D. Camb.

Notes and News

RESETTLING THE DISABLED

HITHERTO hospitals have used the form R.D.1 to notify the Ministry of Labour of patients about to be discharged with residual disability. The Ministry of Health announces in a circular (no. 154/47) that in future this will be used only for Service cases medically boarded at E.M.S. hospitals; otherwise it is to be replaced by a new and simpler form, D.P.55. The circular calls for closer liaison between hospital authorities and the local officers of the Ministry of Labour. Hospitals are urged to acquaint patients with the opportunities that may be found under the Disabled Persons (Employment) Act; and disablement resettlement officers will be on call for visits to hospitals at intervals of not less than three months. At some hospitals medical interviewing committees are to be set up for the purpose of providing resettlement officers with expert medical guidance.

CARE OF BABIES IN THE TROPICS

Dr. John Gibbens has written a capable little pamphlet [1] on the problems which face the young mother in the tropics. His tone is reassuring, but he warns her against likely dangers and teaches her how to become a sanitary inspector, on a small scale, in her own home, how to prevent contamination of food, how to make dangerous foods safe, how to get rid of flies and mosquitoes, and how to arrange the baby's day so as to protect him from heat and yet give him his airings. The notes on milk and milk foods are specially full and competent, and there is also plenty of guidance about the child's clothing and rest, and the care of the skin. The advice on inoculation and on the importance of calling the doctor early in case of illness should be closely followed.

University of Cambridge

During August and September the title of the degrees of M.B., B.CHIR. was conferred on J. M. Cockrell, J. Crossley, H. A. Jaques, M. R. Simpson, and S. G. Wills. The title of the degree of M.B. was also conferred on M. Sutcliffe.

University of Edinburgh

Dr. A. P. Meiklejohn has been appointed lecturer in nutrition in the department of medicine.

Royal College of Obstetricians and Gynæcologists

On Oct. 3 the following were admitted to the fellowship:

G. S. Brown, G. A. Davies, G. P. FitzGerald, A. M. Johns, F. G. McGuinness, Ronald McRobert, R. C. Thomas.

The following were admitted to the membership:

H. B. Bagshaw, G. H. Bancroft-Livingston, Isabella R. Bishop, J. T. S.-Brown, Gwendoline E. Cockrem, J. McD. Corston, G. A. Craig, K. J. R. Cuthbert, G. L. Daly, R. W. Danziger, B. C. Dastur, Josephine A. Davidson, N. E. C. de la Hunt, W. P. G. Dickson, Ian Donald, I. A. Donaldson, Sara M. Field-Richards, T. B. FitzGerald, I. T. Fraser, A. M. Giles, A. McM. Graham, E. F. B. Hamilton, A. J. Hardy, Lois E. Hurter, D. W. James, D. H. Lees, Max Lipsitz, G. I. Louisson, William Love, C. J. MacKinlay, J. T. Mair, Parvati Malkani, Eileen C. Miller, W. G. Mills, P. R. Mitchell, J. D. Murdoch, Mary L. Neville, E. R. Ormerod, H. G. Page, Nancy Perry, E. E. Philipp, J. G. Pritchard, Eric Rawlings, Elizabeth M. Rose, D. A. Fletcher Shaw, D. J. N. Smith, R. A. R. Taylor, James Walker.

Parliamentary Appointment

Mr. Herbert Morrison, Lord President of the Council, has appointed Dr. Stephen Taylor, M.P., to be his parliamentary private secretary.

Ministry of Food

Mr. Norman Wright, D.SC., has been appointed chief scientific adviser to the Minister of Food in succession to Sir Jack Drummond, F.R.S. Dr. Wright has been seconded from his post as director of the Hannah Dairy Research Institute for the duration of his new appointment.

Moyne Institute of Preventive Medicine

As a memorial to the late Lord Moyne, his family are to build and equip an institute of preventive medicine, in Trinity College, Dublin. The institute will provide accommodation for teaching and research in bacteriology and immunology and will also house the new department of social medicine which the college authorities have decided to establish.

1. The Care of Babies and Young Children in the Tropics. National Association of Maternity and Child Welfare Centres, 5, Tavistock Place, London, W.C.1. Pp. 15. 1s.

Deaths.—In 126 great towns there were 3 (1) deaths from enteric fever, 1 (0) from scarlet fever, 1 (0) from measles, 4 (0) from diphtheria, 9 (3) from whooping-cough, 85 (7) from diarrhœa and enteritis under two years, and 5 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 204 (corresponding to a rate of 22 per thousand total births), including 30 in London.

Obituary

ERIK LYSHOLM

Prof. Erik Lysholm, the eminent Swedish radiologist, died in Stockholm on Sept. 26.

The son of a Swedish army officer and of a Scottish mother, he was born in Stockholm in 1891 and educated at Uppsala University. In the early 'twenties he took up radiology in Stockholm, where he worked for the remainder of his life, mainly at the Serafimer Hospital. Stockholm at that time provided suitable soil for Lysholm's growth. When he began the study of radiology that specialty had developed further in Sweden than in any other country. This was largely due to the energy and ability of Prof. Gösta Forssell, the "grand old man" of Swedish radiology. Forssell had an aptitude for picking able pupils and Erik Lysholm was the most able of them all.

Lysholm's first work was to place the radiography of the skull on a sound basis. Good work had already been done in this sphere, notably by Schüller of Vienna, and others had given their names to various special techniques; but there was no standard method of investigation. Furthermore, the quality of skull X-ray films left much to be desired. Lysholm solved these problems with the aid of his mechanical ability and by association with his friend, the engineer, Georg Schonander. The Lysholm precision skull X-ray apparatus has gradually evolved during the last twenty years and is now so good that it is difficult to imagine improvements. A more important contribution to radiography from the fundamental physical aspect was the Lysholm grid. This grid—designed to eliminate scattered X-radiation and thus improve the quality of X-ray pictures—was like many great inventions simple enough in construction, but needed a man of Lysholm's powers to design it. Sometimes known also as the Schonander grid or Swedish grid, it is used in X-ray departments throughout the world.

Neither the skull apparatus nor the grid give any picture of Lysholm's capacity as a doctor. It was always his dictum that radiology should be a form of living morbid anatomy, and the potential truth of this dictum cannot be better illustrated than by his work in neuroradiology. Ventriculography and encephalography had been used for some ten years before Lysholm set to work in studying the possible applications. In the 'twenties brain tumours could be "lateralised," but after working for some ten years on the subject, in association with Olivecrona the neurosurgeon, Lysholm showed that nearly all brain tumours could be exactly localised radiographically, that their size and shape could be displayed, and that often the pathology could be predicted. In 1937 he published his famous monograph, *The Ventriculogram*, based on nearly 500 confirmed cases.

His work in neuroradiology was so outstanding that other lesser advances he made tend to be obscured. For instance, the outlining of the pancreas by filling the stomach with gas was his idea. The accurate measurement of the heart volume was worked out by him some ten years ago, and no better method has been devised since. In later years his main interests were in cineradiology and the use of radioactive isotopes in radiology.

Part of Lysholm's genius was an ability to inspire and stimulate his associates. Many papers from his X-ray department do not bear his name, and in many others he appears only as part author. But his brain was behind the work. Radiologists visited him from all over the world and carried his methods home with them. Though he was by nature shy and modest, his charm and quick wit endeared him to all. After Forssell's retirement from active work some y he directed the Serafimer school of radiology w efficiency in the routine X-ray investigation of combined with scientific advancement, is a model for radiological world.

He leaves a widow, but no children.

HAROLD COURTNEY GAGE

M.R.C.S., F.F.R.

Dr. H. Courtney Gage, director of the radi department at St. Mary's Hospital, London, di Oct. 4 within a few days of his 62nd birthday.

Early in the first world war, while serving with Essex Yeomanry, Courtney Gage was wounded invalided out of the Army. Before 1914 he had as a radiographer with Sir James Mackenzie Dav and he soon returned to France as a captain i American Red Cross to take charge of the radio work at Ris Orangis and at two large French hospitals. His original techniques for the investi of spinal injuries and localisation of foreign bodies appeared in the *Journal de Radiologie*, but in 19 republished the second method in this country *monograph.*

After the war he began his medical studies at Mary's Hospital with the intention of speciali radiology, and when he qualified in 1924 he had be him unrivalled technical experience. Two years he was elected assistant radiologist to St. Mary's and 1935 he was appointed director of the department. was also elected to the staffs of the Hampstead Ge Hospital and St. Luke's Hostel.

Gage's modesty led him perhaps to exaggerate handicap which his deafness would have prove presiding over business, and he preferred to serv specialty as an advisor and counsellor. He w member of the councils of the British Institut Radiology, of the section of radiology of the Royal Soc of Medicine, of the Medical Defence Union, and of British X-ray and Radium Protection Committee. also served as editor of the *British Journal of Radi* and in 1943 when he retired from the chair the insti made him an honorary member. A founder fellow the Faculty of Radiologists, he was the first exam in diagnostic radiology for its fellowship. During late war Gage did much to foster the developmen mass miniature radiography, and for his services to Norwegian forces in this country he was appointe knight of the Royal Order of St. Olaf.

"The stimulus of Gage's unlimited enthusiasm," wri J. A. B., "was infectious, both in radiology and in many hobbies (chief of which were music and pho graphy), and to help his friends he would spare neit time nor pains but gave freely of his vast experie and his many original ideas for which he would acc no credit. As a host he was delightful and genero and with his boyish good humour made each gather a memorable occasion. His almost uncanny wisdom radiology gave the impression that he looked not but through a film and saw behind it the patient." T. H. pays tribute to his gentleness of manner and unchanging kindness, and adds: "Always ready help, Gage was genuinely proud when he was appea to by colleagues either for advice or assistance—no-o enjoyed having his brains picked more than he di and no-one regarded it as a higher privilege to he than he. If honesty of mind, kindness, and patie represent the highest attributes of character Gage m be placed in the front: with these, his quiet assura and wonderful grasp of his specialty made him a m whom no-one could meet without feeling both affecti and respect."

DR. J. C. BRIDGE

A. J. A. writes: "As a very junior and inexperien industrial medical officer, I met Dr. Bridge early in 19 and we formed a friendship at our first meeting whi not only lasted but became stronger as the years pas His profound knowledge of English industry, of indu trial medicine and the law was always at the dispo of all industrial medical officers and indeed of indust nurses throughout the country. One of the first honor

MEDICINE, SCIENCE, AND LEARNING *

HARRY PLATT
M.D. Manc., M.S. Lond., F.R.C.S , F.A.C.S.
PROFESSOR OF ORTHOPÆDIC SURGERY,
UNIVERSITY OF MANCHESTER

THE practice of medicine is now engaged in extending horizon and jurisdiction from the individual, and his nediate needs as an isolate, to the circumstances of social and industrial environment. Such considera-ns at once bring up the important question whether not those who have chosen to follow the vocation of dicine will find themselves adequately equipped meet the new demands of the age which lies before m. The responsibilities which society has come place upon the doctor, as guide, philosopher, and nd in his community, cannot be fulfilled by the r of mere technical skill; nor in fact has craftsman- been the sole or even the main contribution of profession to past generations. I believe that we say with due humility that the profession of medicine by long tradition, at once liberal, scientific, and med. This is not to say that in every practising doctor can yet see both the scholar and the scientist. But does mean that such a man is conscious of the fact it he belongs to a profession which regards such ibutes as its rightful heritage.

THE LIBERAL TRADITION

The tradition of medicine as an independent, self-ning guild, with its own special code of ethics, ne of its most cherished possessions. It is based a sense of sharing in what we feel to be a continuous orical process, extending over a span of more than 00 years from the age of Greek science to the present y. This deeply rooted Hippocratic tradition is in ge part responsible for the individualistic attitude of average doctor, and for his feeling of personal freedom m some of the restraints of society, as exemplified his insistence on the need for the preservation of the ctor-patient relationship, and his instinctive challenge the Law when it conflicts with the Hippocratic code. e these liberal virtues it may be asked? But we are ncerned not with examples of the behaviour of dividuals under certain provocations, but with the tellectual and ethical standards set before a profession ideals to which all are expected to strive to attain.

Walshe (1945), one of the most profound thinkers in itish medicine, has recently come to the conclusion—luctantly I suspect—that medicine is a useful rather an a liberal profession, a view which was also held by ilfred Trotter, the philosopher-surgeon. Walshe has ken as his yard-stick Cardinal Newman's definition of beral knowledge as, among other attributes, "refusing be informed (as it is called) by any end." I find myself n this occasion unconvinced by Walshe's argument. he utilitarian or instrumental rôle of medicine is surely bvious enough, but this description of one of its functions oes not represent the total contribution which medicine s a liberal profession has to offer to the life of the community. The claim of medicine to be regarded as one f the liberal professions cannot be decided on intellectual rounds alone. It is on wider issues that we must be udged. Such are the existence of a corporate sense f values; the acceptance of a historic ethical code hich has fostered a demand for intellectual liberty and elf government; and, not least, the empirical tradition ith its tolerance of new ideas and its ultimate rejection f all dogmatic systems. These, in my judgment, are he liberal virtues on which we confidently base our laim to recognition.

ESSENTIAL FREEDOMS

I have referred to the sense of independence and freedom which for many generations both the doctor as an individual and the profession in its corporate form have come to regard as a natural right. This feeling of membership of a society within society—comparable to the independent 17th-century Puritan society of Grace within the wider society of the State—rests largely on the fact that our right to enjoy our own code of ethics and self-government has not in the past been seriously challenged. But, in the opinion of many, that challenge is implicit in the political climate of Europe today, in which we see the peoples of many nations feverishly and often blindly seeking economic shelter within the framework of collectivist techniques masquerading as ideologies. I myself do not feel unduly pessimistic in this matter. I have great confidence in the influence of a long corporate tradition; and I am impressed by the power of ideas as resistance movements. During the past few years the scientists of the western world have reacted vigorously to the potential threat to their own freedom of thought and action. The tumult—at times rather shrill—of the battle of a free science versus planned science and technology for the moment has died down. But from this conflict there has emerged the important notion of scientists as an independent and self-governing group with an ethical code of their own choosing—a code designed to stand as a perpetual response to the eroding challenge of authoritative doctrines.

Bertrand Russell, in a whimsical and lucid moment of over-simplification, has distinguished two categories of humans as comprising our modern civilisation—those who move pieces of matter about on the face of the earth, and those who order them to do it. We may wonder where the liberal professions come into this drab picture of the managerial revolution. But we should all agree that human societies owe much to the liberal professions, among which I have been bold enough to place medicine. The debt has been amply repaid, for in the past such professions have been accorded a position of special privilege. In a rapidly changing world, where for a brief interlude in the history of man traditional ethical and social values are in the melting-pot, we may ask what privileges a liberal profession can reasonably demand in the future. For the profession of medicine the answer is simple—intellectual freedom and a large measure of self-government. These are not unreasonable demands; they should not be the special possession of an élite preoccupied with its own survival. They are in fact essential to the "good life" in every one of the various groups which make up the mosaic pattern of a true democratic society. It is our duty to proclaim that we intend to preserve such freedoms at all cost.

THE SCIENTIFIC TRADITION

It is a commonplace that the history of the natural sciences throughout the ages, from the era of the flowering of Greek thought down to the latter part of the 19th century, is also the history of medicine. Although the two streams of intellectual activity have pursued an independent existence, they have long been closely intermingled. The contributions of medicine to science and of science to medicine have provided a theme of absorbing interest for many distinguished scholars in our profession—a theme which recurs again in the ceremonial orations of our Royal Colleges. It has been said that Aristotle regarded medicine as a branch of natural science, but Hippocrates, though doubtless influenced by the intellectual climate of his time, was the first great exponent of the clinical method and thus made secure the foundations of medicine as an independent art. For more than 2000 years, medicine, though it has

* Inaugural address at the opening of the winter session of the Welsh National School of Medicine on Sept. 30, 1947.

Royal College of Surgeons of England

At a meeting of the council of the college held on Oct. 9, 1947, with Sir Alfred Webb-Johnson, the president, in the chair, Mr. J. M. Wyatt was coöpted to the council as a representative of gynæcology and obstetrics and was also appointed to represent the college on the Central Midwives Board. The following were elected members of the court of examiners in connexion with specialists' final fellowship examinations:

Mr. M. L. Formby, Mr. V. E. Negus, and Mr. F. C. Ormerod as otolaryngologists; Mr. George Black, Sir Stewart Duke-Elder, and Mr. Frank Law as ophthalmologists. Mr. S. P. Meadows was elected associate examiner in ophthalmology.

The Hallett prize was presented to Dr. Nanalal Jivan Shah (Guy's). Mr. Alexander Livingston (Epsom College) was admitted as a Macloghlin scholar. The award of the Blane medal to Surgeon Commander G. H. G. Southwell-Sander was announced.

The following posts were recognised for the final fellowship examination requirements:

Ashford County Hospital.—Three resident junior house-surgeons and three surgical registrars for a period of one year.

Luton and Dunstable Hospital.—Resident surgical officer and senior house-surgeon for one year.

Hope Hospital, Salford.—Assistant resident surgical officer, assistant medical officer in the department of general surgery, and assistant medical officer of the orthopædic department.

Worcester Royal Infirmary.—Resident surgical officer and two house-surgeons.

Royal Northern Hospital, Inverness.—First and second house-surgeons for a further year.

A diploma in laryngology and otology was granted, jointly with the Royal College of Physicians, to Ben Cohen, and a diploma in ophthalmic medicine and surgery to John McClemont.

Leverhulme Research Scholarships.—Two scholarships of the annual value of £400, with an allowance not exceeding £100 for expenses of research, are vacant. The awards will be made either as scholarships or as grants-in-aid, according to the time available for research work, and they are open to men or women who hold a registrable medical qualification. Scholars must devote themselves to the investigation of some biological or clinical problem of disease as it occurs in man, with a view to the extension of surgical knowledge. Facilities for research will be available in the Bernhard Baron laboratories of the college or at the Buckston Browne Farm, Downe, Kent. Applications should reach the secretary of the college, Lincoln's Inn Fields, London, W.C.2, before Oct. 27.

Children's Moral Welfare Committee

The annual meeting will be held in Hampstead Town Hall on Friday, Oct. 24, at 5.15 P.M., when the speakers will be the Rev. G. L. Russell, M.B., and Miss L. R. Rendel.

Medical Jubilee

On Sept. 24 the colleagues of Dr. W. P. Hay, of Peterborough, gave a dinner in his honour. Dr. Hay set up in practice in the town fifty years ago and is chairman of the Soke of Peterborough insurance committee.

Society of Medical Officers of Health

On Thursday, Oct. 23, at 6 P.M., at B.M.A. House, Tavistock Square, London, W.C.1, Sir Allen Daley, the retiring president, will install Dr. Frederick Hall, M.O.H. for Lancashire, as president of the society for 1947–48. Dr. Hall will afterwards deliver his presidential address on the Economics of Public Health.

Education for Family Life

A conference on this subject will be held at King's College, Strand, London, W.C.2, on Jan. 5 and 6. The four sessions will deal with the home, the formal education system, informal education, and general community influences. Further information may be had from Cyril Bibby, Family Relations Group, 69, Eccleston Square, S.W.1.

Royal Society of Arts

The following Cantor lectures have been arranged for January and February: Dr. C. H. Andrewes, F.R.S., Progress in the Fight against the Common Cold (Jan. 26); Prof. A. C. Frazer, Metabolism of Fats (Feb. 2); and Sir Jack Drummond, D.SC., F.R.S., Fats in the Life of the Nation (Feb. 9). The lectures will all be held at 4.30 P.M. at the house of the society, John Adam Street, London, W.C.2.

Central Midwives Board

Prof. F. E. Tylecote has been elected a member board on the nomination of the Association of M Corporations.

Society of Chemical Industry

A meeting of the nutrition panel will be held at Burl House, Piccadilly, London, W.1, at 6.30 P.M., on We Oct. 29. Prof. Alexander Haddow and Mr. L. A. Elson, will read a paper on Food and Cancer.

CORRIGENDUM.—With regard to his article of (p. 553) on the metric system in medicine, Mr. Finnemore writes: "The abbreviations I recomme my MS. were kilogram, *kgm.*; gramme, *gm.*; m *mgm.*; microgram, *microgm.*; and micromil, *microml.* not advise the use of the Greek letter μ for micro, as I it might lead to mistakes."

Diary of the Week

OCT. 19 TO 25

Monday, 20th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
6.15 P.M. Dr. Robert Cope: Anæsthesia for Babie Children.

EDICINE, SCIENCE, AND LEARNING*

HARRY PLATT
M.D. Manc., M.S. Lond., F.R.C.S., F.A.C.S
PROFESSOR OF ORTHOPÆDIC SURGERY,
UNIVERSITY OF MANCHESTER

HE practice of medicine is now engaged in extending horizon and jurisdiction from the individual, and his nediate needs as an isolate, to the circumstances of social and industrial environment. Such considera- s at once bring up the important question whether not those who have chosen to follow the vocation of licine will find themselves adequately equipped neet the new demands of the age which lies before n. The responsibilities which society has come place upon the doctor, as guide, philosopher, and d in his community, cannot be fulfilled by the r of mere technical skill; nor in fact has craftsman- been the sole or even the main contribution of profession to past generations. I believe that we say with due humility that the profession of medicine by long tradition, at once liberal, scientific, and ned. This is not to say that in every practising doctor can yet see both the scholar and the scientist. But loes mean that such a man is conscious of the fact t he belongs to a profession which regards such ibutes as its rightful heritage.

THE LIBERAL TRADITION

he tradition of medicine as an independent, self- ning guild, with its own special code of ethics, e of its most cherished possessions. It is based sense of sharing in what we feel to be a continuous orical process, extending over a span of more than 0 years from the age of Greek science to the present . This deeply rooted Hippocratic tradition is in e part responsible for the individualistic attitude of average doctor, and for his feeling of personal freedom m some of the restraints of society, as exemplified his insistence on the need for the preservation of the tor-patient relationship, and his instinctive challenge the Law when it conflicts with the Hippocratic code. e these liberal virtues it may be asked? But we are cerned not with examples of the behaviour of ividuals under certain provocations, but with the ellectual and ethical standards set before a profession ideals to which all are expected to strive to attain.

Walshe (1945), one of the most profound thinkers in itish medicine, has recently come to the conclusion— uctantly I suspect—that medicine is a useful rather an a liberal profession, a view which was also held by ilfred Trotter, the philosopher-surgeon. Walshe has ken as his yard-stick Cardinal Newman's definition of eral knowledge as, among other attributes, "refusing be informed (as it is called) by any end." I find myself this occasion unconvinced by Walshe's argument. he utilitarian or instrumental rôle of medicine is surely vious enough, but this description of one of its functions es not represent the total contribution which medicine a liberal profession has to offer to the life of the com- munity. The claim of medicine to be regarded as one the liberal professions cannot be decided on intellectual rounds alone. It is on wider issues that we must be dged. Such are the existence of a corporate sense values; the acceptance of a historic ethical code hich has fostered a demand for intellectual liberty and elf-government; and, not least, the empirical tradition ith its tolerance of new ideas and its ultimate rejection f all dogmatic systems. These, in my judgment, are he liberal virtues on which we confidently base our laim to recognition.

ESSENTIAL FREEDOMS

I have referred to the sense of independence and freedom which for many generations both the doctor as an individual and the profession in its corporate form have come to regard as a natural right. This feeling of membership of a society within society—comparable to the independent 17th-century Puritan society of Grace within the wider society of the State—rests largely on the fact that our right to enjoy our own code of ethics and self-government has not in the past been seriously challenged. But, in the opinion of many, that challenge is implicit in the political climate of Europe today, in which we see the peoples of many nations feverishly and often blindly seeking economic shelter within the framework of collectivist techniques masquerading as ideologies. I myself do not feel unduly pessimistic in this matter. I have great confidence in the influence of a long corporate tradition; and I am impressed by the power of ideas as resistance movements. During the past few years the scientists of the western world have reacted vigorously to the potential threat to their own freedom of thought and action. The tumult—at times rather shrill—of the battle of a free science versus planned science and technology for the moment has died down. But from this conflict there has emerged the important notion of scientists as an independent and self-governing group with an ethical code of their own choosing—a code designed to stand as a perpetual response to the eroding challenge of authoritative doctrines.

Bertrand Russell, in a whimsical and lucid moment of over-simplification, has distinguished two categories of humans as comprising our modern civilisation—those who move pieces of matter about on the face of the earth, and those who order them to do it. We may wonder where the liberal professions come into this drab picture of the managerial revolution. But we should all agree that human societies owe much to the liberal professions, among which I have been bold enough to place medicine. The debt has been amply repaid, for in the past such professions have been accorded a position of special privilege. In a rapidly changing world, where for a brief interlude in the history of man traditional ethical and social values are in the melting-pot, we may ask what privileges a liberal profession can reasonably demand in the future. For the profession of medicine the answer is simple—intellectual freedom and a large measure of self-government. These are not unreasonable demands; they should not be the special possession of an élite preoccupied with its own survival. They are in fact essential to the "good life" in every one of the various groups which make up the mosaic pattern of a true democratic society. It is our duty to proclaim that we intend to preserve such freedoms at all cost.

THE SCIENTIFIC TRADITION

It is a commonplace that the history of the natural sciences throughout the ages, from the era of the flowering of Greek thought down to the latter part of the 19th century, is also the history of medicine. Although the two streams of intellectual activity have pursued an independent existence, they have long been closely intermingled. The contributions of medicine to science and of science to medicine have provided a theme of absorbing interest for many distinguished scholars in our profession—a theme which recurs again in the ceremonial orations of our Royal Colleges. It has been said that Aristotle regarded medicine as a branch of natural science, but Hippocrates, though doubtless influenced by the intellectual climate of his time, was the first great exponent of the clinical method and thus made secure the foundations of medicine as an independent art. For more than 2000 years, medicine, though it has

* Inaugural address at the opening of the winter session of the Welsh National School of Medicine on Sept. 30, 1947.

Royal College of Surgeons of England

At a meeting of the council of the college held on Oct. 9, 1947, with Sir Alfred Webb-Johnson, the president, in the chair, Mr. J. M. Wyatt was coöpted to the council as a representative of gynæcology and obstetrics and was also appointed to represent the college on the Central Midwives Board. The following were elected members of the court of examiners in connexion with specialists' final fellowship examinations:

Mr. M. L. Formby, Mr. V. E. Negus, and Mr. F. C. Ormerod as otolaryngologists; Mr. George Black, Sir Stewart Duke-Elder, and Mr. Frank Law as ophthalmologists. Mr. S. P. Meadows was elected associate examiner in ophthalmology.

The Hallett prize was presented to Dr. Nanalal Jivan Shah (Guy's). Mr. Alexander Livingston (Epsom College) was admitted as a Macloghlin scholar. The award of the Blane medal to Surgeon Commander G. H. G. Southwell-Sander was announced.

The following posts were recognised for the final fellowship examination requirements:

Ashford County Hospital.—Three resident junior house-surgeons and three surgical registrars for a period of one year.

Luton and Dunstable Hospital.—Resident surgical officer and senior house-surgeon for one year.

Hope Hospital, Salford.—Assistant resident surgical officer, assistant medical officer in the department of general surgery, and assistant medical officer of the orthopædic department.

Worcester Royal Infirmary.—Resident surgical officer and two house-surgeons.

Royal Northern Hospital, Inverness.—First and second house-surgeons for a further year.

A diploma in laryngology and otology was granted, jointly with the Royal College of Physicians, to Ben Cohen, and a diploma in ophthalmic medicine and surgery to John McClement.

Leverhulme Research Scholarships.—Two scholarships of the annual value of £400, with an allowance not exceeding £100 for expenses of research, are vacant. The awards will be made either as scholarships or as grants-in-aid, according to the time available for research work, and they are open to men or women who hold a registrable medical qualification. Scholars must devote themselves to the investigation of some biological or clinical problem of disease as it occurs in man, with a view to the extension of surgical knowledge. Facilities for research will be available in the Bernhard Baron laboratories of the college or at the Buckston Browne Farm, Downe, Kent. Applications should reach the secretary of the college, Lincoln's Inn Fields, London, W.C.2, before Oct. 27.

Children's Moral Welfare Committee

The annual meeting will be held in Hampstead Town Hall on Friday, Oct. 24, at 5.15 P.M., when the speakers will be the Rev. G. L. Russell, M.B., and Miss L. R. Rendel.

Medical Jubilee

On Sept. 24 the colleagues of Dr. W. P. Hay, of Peterborough, gave a dinner in his honour. Dr. Hay set up in practice in the town fifty years ago and is chairman of the Soke of Peterborough insurance committee.

Society of Medical Officers of Health

On Thursday, Oct. 23, at 6 P.M., at B.M.A. House, Tavistock Square, London, W.C.1, Sir Allen Daley, the retiring president, will install Dr. Frederick Hall, M.O.H. for Lancashire, as president of the society for 1947–48. Dr. Hall will afterwards deliver his presidential address on the Economics of Public Health.

Education for Family Life

A conference on this subject will be held at King's College, Strand, London, W.C.2, on Jan. 5 and 6. The four sessions will deal with the home, the formal education system, informal education, and general community influences. Further information may be had from Cyril Bibby, Family Relations Group, 69, Eccleston Square, S.W.1.

Royal Society of Arts

The following Cantor lectures have been arranged for January and February: Dr. C. H. Andrewes, F.R.S., Progress in the Fight against the Common Cold (Jan. 26); Prof. A. C. Frazer, Metabolism of Fats (Feb. 2); and Sir Jack Drummond, D.SC., F.R.S., Fats in the Life of the Nation (Feb. 9). The lectures will all be held at 4.30 P.M. at the house of the society, John Adam Street, London, W.C.2.

Central Midwives Board

Prof. F. E. Tylecote has been elected a member board on the nomination of the Association of M Corporations.

Society of Chemical Industry

A meeting of the nutrition panel will be held at Bu House, Piccadilly, London, W.1, at 6.30 P.M., on We Oct. 29. Prof. Alexander Haddow and Mr. L. A. Elson, will read a paper on Food and Cancer.

CORRIGENDUM.—With regard to his article of (p. 553) on the metric system in medicine, Mr. Finnemore writes: "The abbreviations I recomme my MS. were kilogram, *kgm.*; gramme, *gm.*; mi *mgm.*; microgram, *microgm.*; and micromil, *microml.* not advise the use of the Greek letter μ for micro, as I it might lead to mistakes."

Diary of the Week

EDICINE, SCIENCE, AND LEARNING*

HARRY PLATT
M.D. Manc., M.S. Lond., F.R.C.S., F A C S.
PROFESSOR OF ORTHOPÆDIC SURGERY,
UNIVERSITY OF MANCHESTER

HE practice of medicine is now engaged in extending iorizon and jurisdiction from the individual, and his iediate needs as an isolate, to the circumstances of social and industrial environment. Such considera-s at once bring up the important question whether ot those who have chosen to follow the vocation of licine will find themselves adequately equipped neet the new demands of the age which lies before n. The responsibilities which society has come place *upon the doctor, as guide, philosopher, and* id in his community, cannot be fulfilled by the r of mere technical skill; nor in fact has craftsman- been the sole or even the main contribution of profession to past generations. I believe that we say with due humility that the profession of medicine by long tradition, at once liberal, scientific, and hed. *This is not to say that in every practising doctor* can yet see both the scholar and the scientist. But loes mean that such a man is conscious of the fact t he belongs to a profession which regards such ibutes as its rightful heritage.

THE LIBERAL TRADITION

he tradition of medicine as an independent, self- ning guild, with its own special code of ethics, e of its most cherished possessions. It is based a sense of sharing in what we feel to be a continuous orical process, extending over a span of more than 0 years from the age of Greek science to the present . This deeply rooted Hippocratic tradition is in e part responsible for the individualistic attitude of average doctor, and for his feeling of personal freedom m some of the restraints of society, as exemplified his insistence on the need for the preservation of the tor-patient relationship, and his instinctive challenge the Law when it conflicts with the Hippocratic code. these liberal virtues it may be asked? But we are ncerned not with examples of the behaviour of ividuals under certain provocations, but with the ellectual and ethical standards set before a profession ideals to which all are expected to strive to attain.

Walshe (1945), one of the most profound thinkers in itish medicine, has recently come to the conclusion— uctantly I suspect—that medicine is a useful rather an a liberal profession, a view which was also held by lfred Trotter, the philosopher-surgeon. Walshe has ken as his yard-stick Cardinal Newman's definition of eral knowledge as, among other attributes, "refusing be informed (as it is called) by any end." I find myself n this occasion unconvinced by Walshe's argument. he utilitarian or instrumental rôle of medicine is surely bvious enough, but this description of one of its functions oes not represent the total contribution which medicine s a liberal profession has to offer to the life of the com- unity. The claim of medicine to be regarded as one f the liberal professions cannot be decided on intellectual rounds alone. It is on wider issues that we must be udged. Such are the existence of a corporate sense f values; the acceptance of a historic ethical code hich has fostered a demand for intellectual liberty and elf-government; and, not least, the empirical tradition ith its tolerance of new ideas and its ultimate rejection f all dogmatic systems. These, in my judgment, are the liberal virtues on which we confidently base our claim to recognition.

ESSENTIAL FREEDOMS

I have referred to the sense of independence and freedom which for many generations both the doctor as an individual and the profession in its corporate form have come to regard as a natural right. This feeling of membership of a society within society—comparable to the independent 17th-century Puritan society of Grace within the wider society of the State—rests largely on the fact that our right to enjoy our own code of ethics and self-government has not in the past been seriously challenged. But, in the opinion of many, that challenge is implicit in the political climate of Europe today, in which we see the peoples of many nations feverishly and often blindly seeking economic shelter within the framework of collectivist techniques masquerading as ideologies. I myself do not feel unduly pessimistic in this matter. I have great confidence in the influence of a long corporate tradition; and I am impressed by the power of ideas as resistance movements. During the past few years the scientists of the western world have reacted vigorously to the potential threat to their own freedom of thought and action. The tumult—at times rather shrill—of the battle of a free science versus planned science and technology for the moment has died down. But from this conflict there has emerged the important notion of scientists as an independent and self-governing group with an ethical code of their own choosing—a code designed to stand as a perpetual response to the eroding challenge of authoritative doctrines.

Bertrand Russell, in a whimsical and lucid moment of over-simplification, has distinguished two categories of humans as comprising our modern civilisation—those who move pieces of matter about on the face of the earth, and those who order them to do it. We may wonder where the liberal professions come into this drab picture of the managerial revolution. But we should all agree that human societies owe much to the liberal professions, among which I have been bold enough to place medicine. The debt has been amply repaid, for in the past such professions have been accorded a position of special privilege. In a rapidly changing world, where for a brief interlude in the history of man traditional ethical and social values are in the melting-pot, we may ask what privileges a liberal profession can reasonably demand in the future. For the profession of medicine the answer is simple—intellectual freedom and a large measure of self-government. These are not unreasonable demands; they should not be the special possession of an élite preoccupied with its own survival. They are in fact essential to the "good life" in every one of the various groups which make up the mosaic pattern of a true democratic society. It is our duty to proclaim that we intend to preserve such freedoms at all cost.

THE SCIENTIFIC TRADITION

It is a commonplace that the history of the natural sciences throughout the ages, from the era of the flowering of Greek thought down to the latter part of the 19th century, is also the history of medicine. Although the two streams of intellectual activity have pursued an independent existence, they have long been closely intermingled. The contributions of medicine to science and of science to medicine have provided a theme of absorbing interest for many distinguished scholars in our profession—a theme which recurs again in the ceremonial orations of our Royal Colleges. It has been said that Aristotle regarded medicine as a branch of natural science, but Hippocrates, though doubtless influenced by the intellectual climate of his time, was the first great exponent of the clinical method and thus made secure the foundations of medicine as an independent art. For more than 2000 years, medicine, though it has maintained its identity, has been intimately linked to the natural sciences. It is thus not surprising that the art of medicine, with its attachment to the great empirical tradition, should bear the imprint of the scientific method.

---

* Inaugural address at the opening of the winter session of the Welsh National School of Medicine on Sept. 30, 1947.

It is customary to speak, however, of the art and science of medicine as two separate activities or systems; and the belief still lingers that a fundamental distinction can be drawn between the so-called practical doctor and the medical scientist. It was Disraeli who said that the quality of a practical man is that he makes the same mistakes as his grandfather. And Harvey Cushing often quoted Abraham Flexner's dictum that the chief difference between the practical and the scientific doctor is that the latter is less likely to lose his patient. Therefore though medicine still remains an art, to be taught by precept and example, even for the practical doctor it must be continuously informed by the methodology of science.

CLINICAL SCIENCE

One of the outstanding contributions of British medicine during the last thirty years has been the creation, under the inspiration and leadership of the late Sir Thomas Lewis, of a school of clinical scientists trained to study the phenomena of disease by the precise methods of the physiological laboratory. As Lewis (1933) pointed out in his Harveian Oration, the practice of clinical science was a return to the method of Harvey himself, who combined clinical observations with animal experiments. It was Lewis's view that, given the liberty to pursue knowledge for its own sake, the clinical scientists would lead the medical scientists in the future. But it was not his wish to see a break away from medicine and the emergence of a separate discipline—indeed of a separate art. If this were to happen it would leave the standards of medicine at the mercy of the so-called practical man denied the inspiration which comes from a feeling of fellowship in the world of science and learning. In this renaissance of clinical science as an integral part of medicine we see how deeply rooted is the scientific tradition of our calling.

It is, therefore, not difficult to trace the origin of the scientific tradition in medicine, and to see in the activities of the practising clinician glimpses of the scientific method, defined long ago by Karl Pearson (1892) lucidly but not euphoniously as "the accurate classification of facts and observation of their correlation and sequence." The practical doctor would be a poor thing if he were ignorant of the scientific approach to the problems of diagnosis and prognosis which confront him.

For the educated practitioner of the future, if freed from much of the drudgery of his traditional handicraft by the provision of technical assistance, and given time to observe, to record, and to use the instrument of his mind in a patient search for a synthesis of ideas, there looms a unique opportunity of enriching our knowledge concerning the phenomena of health and disease. This should be particularly true of the country doctor, who is in many respects still the flower of our profession. The great examples of James Mackenzie in the past, and of William Pickles in the present generation, should surely inspire many followers.

But we may ask whether the modern education and training of the student of medicine is designed to produce, or at least foster the emergence of, future Mackenzies. Theoretically it would seem impossible today for a student to reach the stage of clinical studies lacking a clear understanding of the meaning of the historical and scientific methods. But it is by no means certain that teachers in the preclinical sciences, as a body, feel any special responsibility for the scientific and cultural outlook of the future doctor. Many are content with the presentation of facts in an attractive setting. There are notable exceptions, of course, and it is a delight to the clinical teacher to meet the student fresh from such inf brimful of factual knowledge which the young m acquires with such ease, but already aware of significance of wide generalisations. If the prec teachers fail in this task, how can the part-time c teacher, whose episodic function is to present an en new mass of brute facts, make good such a deficiency

A PHILOSOPHY OF MEDICINE

It might be maintained that the enjoyment of a association with science, and the habitual use of so the techniques of the scientific method, merely medicine to claim the status of an applied scienc that there the matter rests. Some would be co with this judgment, for it suggests at least an hono estate in the community. But to the questing sp those in our profession who are blessed—or perh times even cursed—by what Almroth Wright de as a "pain in the mind," this is not the ultimate of a learned profession. Walshe has deplored the occupation with the collection of facts which now to be the outstanding activity of medicine and ancillary experimental sciences. He emphasises need for a period devoted to interpretation and synth —a return to an age of reason. Only in this way do Walshe consider it will be possible at some future ti to construct a coherent science and art of medicin a true philosophy of medicine, resting securely on body of general principles of wide validity. He believ that such generalisations should come from the rea of clinical studies, as they have done in the past in fields of neurology and cardiology.

A fascinating task thus lies before us which repre a much-needed challenge to the tendency to rest com cently on the empirical tradition and to be content a far too narrow conception of the application of scientific method in the study of the phenomena disease. Since the days of Galen's great essay Medical Experience (*circa* A.D. 150), both the practi and the scientific men of medicine have fought shy general principles formulated by the exercise of th intellect alone. This instinctive and powerful resistanc to rationalism in medicine has no doubt been promp by the knowledge that the enunciation of so-called gene principles has often in the past led to the setting up dogmatic systems of thought and practice. The wor of Harvey have sounded a note of warning for 300 years "I profess to learn and to teach anatomy, not fro books but from dissection, not from the positions philosophers but from the fabric of nature." A John Hunter, that master of observation and exp ment—himself a man of little learning and untouch by the intellectual splendour of the age in which he li —had no doubt where he stood in this matter: " man who judges from general principles only, sho ignorance; few things are so simple as to come who within a general principle." Be that as it may, practical men of the modern age have not been slow by the aid of some mysterious intellectual process, elevating technique to the level of principles. In t distortion of the art of reasoning, often disguised outpourings of emotional prose, members of my o craft, the surgeons, have been and continue to be t chief offenders.

The task of creating a science and philosophy medicine is the responsibility of our profession alone. We cannot expect to delegate our abstract thinking the scientists and humanists. We teachers in medicin must strive to inculcate in our students that attitude mind described by Whitehead as "an interest in the relation of general principles to irreducible and stubborn facts." I am confident that, by reason of its long intellectual and scientific tradition, the profession of medicine will continue to produce and foster those inkers—few though they may be—whose primary ntributions will lie in the integration of knowledge.

THE LEARNED TRADITION

In every generation our profession has contained en distinguished by their wide learning who have ercised an influence on our intellectual aims out of proportion to their numbers. This was perhaps more ue of the generations immediately behind us when a manistic education was accepted as the natural proach to the study of medicine, and before the modern amination system had encouraged precocious specialisa- n. It is, however, no part of my present purpose to ell on the contributions to our ethos of a few men of standing learning. In a profession which maintains ively appreciation of the true value of hero worship ch men are not easily forgotten. I am concerned ther to consider the means whereby we can ensure that liberal education is an essential part of the equip- nt of all who choose to engage in the practice of medi- e: and to discuss how far it is possible to regard dicine itself as one of the cultural disciplines of a iversity education.

Judged by modern standards, the four subjects of the vanced education of the Middle Ages—astronomy, ometry, arithmetic, and music—seem to be an affair extreme simplicity. But every educated man of that me was expected to be well versed in at least one anch of physical science. Thus science established elf as part of the content of a liberal education long o. Indeed, as Sir Richard Livingstone (1947) has ntly reminded us, the modern distinction between ce and humanism would have been meaningless to e Greeks. The humanists and scientists are, however, longer in serious conflict regarding the essential content a liberal education. All are agreed that a liberal educa- on, with its emphasis on the value of balanced scholar- ip, is the proper avenue of approach to all the specialised orms of learning. Sir Richard Livingstone would anslate this notion into practice by a reform of the cholarship system whereby complete specialism in the tage of education which follows the school certificate ould be prohibited. Broadly speaking this means that he humanists would be required to receive a basic ducation in science, and the scientists would spend some me in humanistic studies as a major subject. But this, o Sir Richard, would be but a partial solution of the rger problem of making certain that the essence of liberal education would permeate the years of specialist udies in the universities. He has looked for a cultural iscipline which would form a bond between the under- raduates in all faculties, and this he finds in the ompulsory study of philosophy. Other distinguished cholars and educationists who have thought deeply on this important matter may have other solutions to offer, which may differ perhaps in detail but are unlikely to differ in principle.

LIBERAL EDUCATION AS AN APPROACH TO MEDICINE

Such notions should find warm support from the teachers of medicine; for under our present system the would-be medical student is effectively segregated as a “ specialist ” at a comparatively tender age. To the average boy or girl, the successful storming of the portal of entry to one of the older universities through the 1st M.B., or to “ Redbrick ” through the higher certificate, involves a period of intensive ingestion of a large mass of factual information in the basic sciences which leaves scanty time for any other form of intellectual activity. It is, of course, true that there are compensating influences at work. Inherited tastes, and the outlook nurtured by the traditions and background of a cultivated home life, are powerful antidotes to the deadening effect of a predominantly technological discipline. These advantages are, however, the possession of a fortunate minority. It is our duty to ensure that such influences continue to be represented in the aspirants to a learned profession. But we must continue to face the fact that today medicine is largely recruited from a group of young people whose “general” education finishes between the age of 15 and 16 or even earlier. The classical scholar who, at the age of 18, feels the urge to enter the profession of medicine is confronted by the formidable obstacles of a delaying action. He and others like him do not fit into the rigid scheme of a narrow portal of entry. Looking back to my own student days, my most brilliant contemporary, who is now one of the outstanding scholars in British medicine, made his first acquaintance with a test-tube and a laboratory bench on the day he entered the medical school.

It is important that we should do more than pay lip service to the idea that a liberal education is the essential prologue to the study of medicine, and that the portals of entry should be kept wide open. As a self-governing profession we have the power to embark on educational reforms, but the pace of our administrative machinery is in keeping with the modern age, and ideas issue slowly into action. When we ask how throughout the six long years of undergraduate education the student of medicine can be made to feel that he is not only being trained for a high vocation but is engaged in the pursuit of learning for its own sake, we find a situation full of difficulties. In so far as the teaching of medicine is increasingly based on the methodology of science, and the generalisations of science are regarded as having a cultural value of their own, the intellectual foundations of our art appear to be well secured. But the scientists are demanding a wider content of education for themselves, and it should not be difficult, as Sir Richard Livingstone has shown, for the universities to meet their needs. But he would be a bold man who, at this juncture, attempted to introduce into the intensive and overcrowded curriculum of the student of medicine *compulsory* courses of study in “ cultural ” subjects.

We are driven to the conclusion that for the preservation of the intellectual standards of our profession we cannot look to any single comprehensive plan. The intellectual tradition is there to be nurtured and reinterpreted to each succeeding generation. The impact of teachers who are men of wide learning on the receptive minds of students with a liberal education behind them will ensure that the flame of scholarship is something more than a mere flicker. Medicine, in its widest sense, must therefore strive continually to become a cultural discipline in its own right within the larger pattern of university education.

MEDICINE IN THE UNIVERSITIES

Fears have been expressed that the impending invasion of the universities by larger numbers of medical students will tend to undermine still further the humanist traditions already threatened by the predominance of the science faculties. Some feel that medicine should therefore be confined within the walls of its own technological institutions. If this came to pass it would be a disaster both for medicine and the universities. The universities have a dual responsibility in this matter. They have first of all inherited from the independent schools of medicine, which they absorbed in the 19th century, the function of providing a vocational training for the medical student. In this they are fulfilling a humanitarian function not unworthy of their highest traditions, for they are concerned with the quality of that large and important group of university graduates who are destined to serve the community as family doctors. These are the men and women whose life work has been so well described in the words of one of the pioneer medical women in the United States of America—

"*to cure sometimes, to relieve often, and to comfort always*" (Withington 1945). The second responsibility of the universities towards physic—which be it remembered was one of the three faculties of the medieval universities—is to see to it that the medical graduates are in truth members of a learned profession. It is said that, on degree days, the great President Eliot of Harvard always addressed the graduands in the following formula: "Gentlemen, today I welcome you to the great company of educated men." It may be true that his audience always contained a goodly proportion of young men whose intellectual activities were shortly to be displayed in the affairs of the stock market. But the message was clear, and it is this message that we as doctors want from the universities. The student of medicine, just as much as every other undergraduate, needs the education which only a university can give—that integration of the manifold aspects of knowledge and experience which teaches the art of living.

Medicine must therefore remain within the university societies of scholars and students, not only as a means of preserving and enhancing its intellectual traditions but in order that as one form of liberal learning it may make its own contribution to the common pool of university scholarship.

From time to time it has been suggested that the scientific and intellectual aims of medicine would be best served by the creation in each university of an honours school to provide for the handful of brilliant students who are to be found in every year. In another version of the same theme it is suggested that one complete university medical school might be set aside for this purpose. At first glance the idea is most attractive. But I am one of those who regard the deliberate creation of an élite within the profession as fraught with grave danger to the standards of medicine. There are two main objections to such a policy. First, it would perpetuate the false disjunction between the practical man and the scientific doctor of which I have already spoken, and the profession as a whole would soon cease to merit the titles of scientific and learned. Secondly, under the spell of the present trend in the teaching of medicine, an honours school would merely provide an opportunity for the presentation of an additional mass of factual information. No; the mark of a learned profession is that it sets the ideal of scholarship as the common goal of all its members. In medicine we must stand or fall on our corporate traditions and aims.

THE UNIVERSITY HOSPITAL

So far I have dealt with the theme of medicine in its university setting in broad outline only. But we have to remind ourselves that, during three critical years, the student of medicine spends a large part of his working day in a teaching hospital. Here for the first time he comes under the full influence of the humanitarian traditions which give him a sense of vocation. But the hospital is also an institution in which the study and practice of handicraft tends to dominate the scene. The student is now called on to become a man of action, and he is taught the important lesson that this is one of the attributes of the "good doctor." Such a background is an appropriate setting for an education in the art of medicine. It is not surprising however that the atmosphere of the teaching hospital tends to be either intellectually neutral or is at times strongly tinged with anti-intellectualism. But the essential scholarship of medicine need not wither away in such an environment if clinical teachers are selected for the quality of their learning. How can this be ensured?

Under the traditional hospital system of Great Britain the influence of the universities on the intellectual standards of clinical teaching has, with notable exceptions, [illegible] indirect and often negligible. Nearly fifty years have elapsed since the first true university was established in an English-speaking country may recall the words of William Osler on this mom event: "*The opening of the Johns Hopkins H in 1889 marked a new departure in medical ed in the United States of America. It was not the h itself . . . it was not the men . . . it was the organis* We still await the advent of a *university hosp* Great Britain; and by this I mean one in wh *clinical pattern of staffing* as well as the appointm the entire staff is the *responsibility of the uni* alone. To those of us who have cherished the i the university hospital for many years, the mendations of the Goodenough Committee i respect brought a sense of deep frustration. Th in the report of the "inevitability of gradua does not satisfy our impatience. Nor does the co tion of the governing bodies of the teaching hosp laid down in the New Health Act, where the representation of the university is but a fifth total members, seem to bring nearer the consumm of our heart's desire.

In Great Britain *there is strong opposition* to the concept of a university hospital, an opposition if ever based on first-hand experience of the work the system in other countries. Nevertheless I convinced that the transformation of the te hospitals of Great Britain into true university ho would do more than any other single act of ref medical education to ensure that our successor indeed be members of a liberal, scientific, and l profession.

ACUTE SUPPURATIVE TENOSYNOVI TREATED WITH SYSTEMIC PENICI

C. NIGEL CRUICKSHANK
M.B. St. And.
MEMBER OF THE MEDICAL RESEARCH COUNCIL INDUS MEDICINE RESEARCH UNIT

STEWART H. HARRISON
F.R.C.S.
SURGEON
BIRMINGHAM ACCIDENT HOSPITAL

INFECTIONS of the hand following minor injury long been recognised as an important cause of perm disablement and of serious loss of industrial time. reduction of this wastage should become possible the increased production of penicillin.

Acute suppurative tenosynovitis is probably the damaging of the hand infections, and at this hosp is seen largely as an industrial complaint. To tes effectiveness of intramuscular penicillin in this con an investigation was carried out on all the cases tr during 1946 by one of the four surgeons (S. H. The clinical diagnosis was confirmed in each ca operation; 10 of the 13 cases were frankly purule operation, but the minimal criterion for inclusion the presence of an excess of clear fluid in the s at operation. This occurred in 1 case *secondar* a *pulp infection*, and culture subsequently yi *Staph. aureus.*

In 9 cases there was a history of minor injury, a 8 of these the injury had been incurred in the cou the patient's work. The injuries ranged from a comp fracture of the terminal phalanx to apparently t atches and swarf injuries. In 3 cases there were ical primary tendon-sheath infections, the remainder ng complications of either finger-pulp infections (8 es) or superficial abscesses (2 cases).

The infecting organism in all 3 of the primary tendon-ath infections was *Strep. pyogenes*. In the secondary es the predominant organism was *Staph. aureus* either ne or in mixed culture with other organisms, *Strep. genes* being associated with it in 3 cases.

TREATMENT

The treatment was uniform as far as the clinical ndition would permit. The three main principles hered to were minimal incision, systemic penicillin, d early active movements.

As soon as the diagnosis was made, the sheath was sed in the palm to relieve tension. Where there was uperficial abscess in the finger communicating with sheath it was opened at that point also.

Intramuscular penicillin was given immediately after ration in three-hourly doses of 12,500 units and tinued until 1,000,000 units had been given in ten s. By this time the patients were usually fit for charge and outpatient surveillance. There was one ception to this plan of treatment: this patient received y a five-day course of 100,000 units daily and was scharged on the sixth day.

It was apparent in the cases treated early in the series at movement caused little distress; so the patients re encouraged to exercise their fingers on the day er operation.

CONTROLS

In view of the encouraging results with local penicillin ported by Florey and Williams (1944) it was not sidered justifiable to deprive any patients of penicillin r control purposes. To gain a standard of comparison e clinical records of 13 unselected cases of tendon-eath infection treated at this hospital during 1943 in re-penicillin days were investigated. They differed om the present series not only in regard to chemo-erapy but also in the method of surgical approach. ulphonamides were used in a proportion of these cases ithout any appreciable effect on the end-result. These ases can in no wise be regarded as controls, but their e is justified in that they give a measure of the results f acute tendon-sheath infection before penicillin was used.

RESULTS

The end-results of treatment were divided into four ategories:

(1) "Full" indicating full function and including 2 cases here there was a very slight limitation of full extension at he distal interphalangeal joint.

(2) "Fair" indicating fair movement and a useful finger ough the range was limited.

(3) "Stiff" indicating a stiff finger but not so useless as o warrant amputation.

(4) "Amputation"—those requiring amputation.

The results were as follows:

1946	*Full*	*Fair*	*Stiff*	*Amputation*	*Not known*
Penicillin ..	8	2	1	1	1*
1943					
No penicillin	0	2	2	9	0

* While still under outpatient observation at this hospital this patient, who also had tabes dorsalis, was admitted to another hospital with pneumonia and subsequently died.

In no case in the present series was the function of the rest of the hand impaired, though this was a common occurrence before pencillin was used.

Among the patients who recovered full movement the time required for this to take place varied from 3 weeks to 3 months, without any apparent reason.

Complications and Healing-time

In the penicillin-treated cases the subsidence of the acute stage of infection and the relief of subjective symptoms were rapid. No proximal spread of infection took place, and the only complication which arose was the sloughing of the tissues immediately surrounding the area of original infection. Soft-tissue slough developed in 3 cases, of which 1 required skin-grafting. Gangrene of the tip of the finger developed in 1 case, necessitating amputation through the middle phalanx. This was performed on the seventh day, penicillin having controlled the infective process by then.

The median healing-time was 27 days, with a maximum of 38 and a minimum of 12.

In the records investigated for purposes of comparison, only 3 cases showed uncomplicated recovery. The remainder gave a postoperative history of cellulitis, arthritis, and repeated drainage operations, causing a great load on the hospital services. The median healing-time was 61 days, with a maximum of 180 days and a minimum of 17.

DISCUSSION

The effectiveness of repeated intramuscular injection of penicillin is well established by these results. Instead of being in serious danger of losing finger and even life, the patient with acute suppurative tenosynovitis should now have an excellent chance of regaining a fully functional finger. The results are an improvement on those reported by Florey and Williams (1944) using local penicillin and are of the same order as those reported by Curr (1945), who administered penicillin by continuous intramuscular drip giving, in a five-day course, a total dosage of 500,000 units. Pilcher (1946) reported 3 cases treated by repeated injection of large doses of penicillin and obtained full functional recovery in each case.

We can confirm the finding of Curr (1945) that the presence of pus in the sheath made no difference to the end-result. In 1 case the attachment of the tendon to the base of the terminal phalanx was greenish, and in pre-penicillin days its viability would have been in serious doubt. This patient recovered full function, the range of movement at the terminal interphalangeal joint being only slightly limited.

The reason for the comparative failure of treatment in 4 cases is not clear. Penicillin was administered soon after symptoms appeared. They were all streptococcal infections, but 2 other cases which were likewise streptococcal obtained full function. These patients, however, were all over 55 years of age, and the difficulty of rehabilitating the patient of this age after a finger injury may explain the poor result.

On general grounds it is felt that larger doses might give still better results, and that the duration of the course might possibly be shortened. Whether larger doses of penicillin will eliminate some of the failures is being made the subject of a further study.

The fact that 10 of the cases treated last year were secondarily infected sheaths serves once more to emphasise the importance of so-called minor sepsis of the fingers. Current studies of pulp infections of the finger in this hospital have shown that systemic penicillin reduces the incidence of complications. The increasing use of penicillin in septic conditions of the fingers should reduce the incidence of secondary tendon-sheath infections, which now must be regarded as largely preventable.

SUMMARY

The results of treating 13 consecutive cases of acute suppurative tenosynovitis of the finger with intramuscular penicillin during 1946 are reported. These results are contrasted with those obtained in an equal number of randomly selected cases treated without penicillin in 1943.

"to cure sometimes, to relieve often, and to comfort always" (Withington 1945). The second responsibility of the universities towards physic—which be it remembered was one of the three faculties of the medieval universities —is to see to it that the medical graduates are in truth members of a learned profession. It is said that, on degree days, the great President Eliot of Harvard always addressed the graduands in the following formula: "Gentlemen, today I welcome you to the great company of educated men." It may be true that his audience always contained a goodly proportion of young men whose intellectual activities were shortly to be displayed in the affairs of the stock market. But the message was clear, and it is this message that we as doctors want from the universities. The student of medicine, just as much as every other undergraduate, needs the education which only a university can give—that integration of the manifold aspects of knowledge and experience which teaches the art of living.

Medicine must therefore remain within the university societies of scholars and students, not only as a means of preserving and enhancing its intellectual traditions but in order that as one form of liberal learning it may make its own contribution to the common pool of university scholarship.

From time to time it has been suggested that the scientific and intellectual aims of medicine would be best served by the creation in each university of an honours school to provide for the handful of brilliant students who are to be found in every year. In another version of the same theme it is suggested that one complete university medical school might be set aside for this purpose. At first glance the idea is most attractive. But I am one of those who regard the deliberate creation of an élite within the profession as fraught with grave danger to the standards of medicine. There are two main objections to such a policy. First, it would perpetuate the false disjunction between the practical man and the scientific doctor of which I have already spoken, and the profession as a whole would soon cease to merit the titles of scientific and learned. Secondly, under the spell of the present trend in the teaching of medicine, an honours school would merely provide an opportunity for the presentation of an additional mass of factual information. No; the mark of a learned profession is that it sets the ideal of scholarship as the common goal of all its members. In medicine we must stand or fall on our corporate traditions and aims.

THE UNIVERSITY HOSPITAL

So far I have dealt with the theme of medicine in its university setting in broad outline only. But we have to remind ourselves that, during three critical years, the student of medicine spends a large part of his working day in a teaching hospital. Here for the first time he comes under the full influence of the humanitarian traditions which give him a sense of vocation. But the hospital is also an institution in which the study and practice of handicraft tends to dominate the scene. The student is now called on to become a man of action, and he is taught the important lesson that this is one of the attributes of the "good doctor." Such a background is an appropriate setting for an education in the art of medicine. It is not surprising however that the atmosphere of the teaching hospital tends to be either intellectually neutral or is at times strongly tinged with anti-intellectualism. But the essential scholarship of medicine need not wither away in such an environment if clinical teachers are selected for the quality of their learning. How can this be ensured?

Under the traditional hospital system of Great Britain the influence of the universities on the intellectual standards of clinical teaching has, with notable exceptions, always been indirect and often negligible. Nearly fifty years have elapsed since the first true university was established in an English-speaking country. may recall the words of William Osler on this mom event: "The opening of the Johns Hopkins H in 1889 marked a new departure in medical edu in the United States of America. It was not the h itself . . . it was not the men . . . it was the organisa We still await the advent of a university hospi Great Britain; and by this I mean one in which clinical pattern of staffing as well as the appointment the entire staff is the responsibility of the univ alone. To those of us who have cherished the ideal the university hospital for many years, the mendations of the Goodenough Committee in respect brought a sense of deep frustration. The in the report of the "inevitability of gradual does not satisfy our impatience. Nor does the co tion of the governing bodies of the teaching hospi laid down in the New Health Act, where the representation of the university is but a fifth of total members, seem to bring nearer the consumm of our heart's desire.

In Great Britain there is strong opposition to the wh concept of a university hospital, an opposition rar if ever based on first-hand experience of the working the system in other countries. Nevertheless I rem convinced that the transformation of the teachi hospitals of Great Britain into true university hospital would do more than any other single act of reform i medical education to ensure that our successors w indeed be members of a liberal, scientific, and lear profession.

ACUTE SUPPURATIVE TENOSYNOVITIS TREATED WITH SYSTEMIC PENICILLIN

C. Nigel Cruickshank
M.B. St. And.
MEMBER OF THE MEDICAL RESEARCH COUNCIL INDUSTRIAL MEDICINE RESEARCH UNIT

Stewart H. Harrison

BIRMINGHAM ACCIDENT HOSPITAL

Infections of the hand following minor injury hav long been recognised as an important cause of permanent disablement and of serious loss of industrial time. Th reduction of this wastage should become possible wit the increased production of penicillin.

Acute suppurative tenosynovitis is probably the mo damaging of the hand infections, and at this hospital i is seen largely as an industrial complaint. To test the effectiveness of intramuscular penicillin in this condition an investigation was carried out on all the cases treated during 1946 by one of the four surgeons (S. H. H.). The clinical diagnosis was confirmed in each case at operation; 10 of the 13 cases were frankly purulent at operation, but the minimal criterion for inclusion wa the presence of an excess of clear fluid in the sheath at operation. This occurred in 1 case secondary to a pulp infection, and culture subsequently yielded *Staph. aureus.*

In 9 cases there was a history of minor injury, and in 8 of these the injury had been incurred in the course of the patient's work. The injuries ranged from a compound fracture of the terminal phalanx to apparently trivial uches and swarf injuries. In 3 cases there were ical primary tendon-sheath infections, the remainder ng complications of either finger-pulp infections (8 es) or superficial abscesses (2 cases).

The infecting organism in all 3 of the primary tendon-ath infections was *Strep. pyogenes*. In the secondary es the predominant organism was *Staph. aureus* either ne or in mixed culture with other organisms, *Strep. genes* being associated with it in 3 cases.

TREATMENT

The treatment was uniform as far as the clinical dition would permit. The three main principles ered to were minimal incision, systemic penicillin, d early active movements.

s soon as the diagnosis was made, the sheath was ed in the palm to relieve tension. Where there was uperficial abscess in the finger communicating with sheath it was opened at that point also.

ntramuscular penicillin was given immediately after ration in three-hourly doses of 12,500 units and tinued until 1,000,000 units had been given in ten ys. By this time the patients were usually fit for charge and outpatient surveillance. There was one ception to this plan of treatment: this patient received ly a five-day course of 100,000 units daily and was charged on the sixth day.

It was apparent in the cases treated early in the series at movement caused little distress; so the patients re encouraged to exercise their fingers on the day er operation.

CONTROLS

n view of the encouraging results with local penicillin rted by Florey and Williams (1944) it was not sidered justifiable to deprive any patients of penicillin r control purposes. To gain a standard of comparison e clinical records of 13 unselected cases of tendon-eath infection treated at this hospital during 1943 in re-penicillin days were investigated. They differed om the present series not only in regard to chemo-erapy but also in the method of surgical approach. ulphonamides were used in a proportion of these cases ithout any appreciable effect on the end-result. These ses can in no wise be regarded as controls, but their e is justified in that they give a measure of the results f acute tendon-sheath infection before penicillin was used.

RESULTS

The end-results of treatment were divided into four ategories:

(1) "Full" indicating full function and including 2 cases here there was a very slight limitation of full extension at he distal interphalangeal joint.

(2) "Fair" indicating fair movement and a useful finger ough the range was limited.

(3) "Stiff" indicating a stiff finger but not so useless as o warrant amputation.

(4) "Amputation"—those requiring amputation.

The results were as follows:

	Full	*Fair*	*Stiff*	*Amputation*	*Not known*
1946					
Penicillin ..	8	2	1	1	1*
1943					
No penicillin	0	2	2	9	0

* While still under outpatient observation at this hospital this patient, who also had tabes dorsalis, was admitted to another hospital with pneumonia and subsequently died.

In no case in the present series was the function of the rest of the hand impaired, though this was a common ccurrence before pencillin was used.

Among the patients who recovered full movement the time required for this to take place varied from 3 weeks to 3 months, without any apparent reason.

Complications and Healing-time

In the penicillin-treated cases the subsidence of the acute stage of infection and the relief of subjective symptoms were rapid. No proximal spread of infection took place, and the only complication which arose was the sloughing of the tissues immediately surrounding the area of original infection. Soft-tissue slough developed in 3 cases, of which 1 required skin-grafting. Gangrene of the tip of the finger developed in 1 case, necessitating amputation through the middle phalanx. This was performed on the seventh day, penicillin having controlled the infective process by then.

The median healing-time was 27 days, with a maximum of 38 and a minimum of 12.

In the records investigated for purposes of comparison, only 3 cases showed uncomplicated recovery. The remainder gave a postoperative history of cellulitis, arthritis, and repeated drainage operations, causing a great load on the hospital services. The median healing-time was 61 days, with a maximum of 180 days and a minimum of 17.

DISCUSSION

The effectiveness of repeated intramuscular injection of penicillin is well established by these results. Instead of being in serious danger of losing finger and even life, the patient with acute suppurative tenosynovitis should now have an excellent chance of regaining a fully functional finger. The results are an improvement on those reported by Florey and Williams (1944) using local penicillin and are of the same order as those reported by Curr (1945), who administered penicillin by continuous intramuscular drip giving, in a five-day course, a total dosage of 500,000 units. Pilcher (1946) reported 3 cases treated by repeated injection of large doses of penicillin and obtained full functional recovery in each case.

We can confirm the finding of Curr (1945) that the presence of pus in the sheath made no difference to the end-result. In 1 case the attachment of the tendon to the base of the terminal phalanx was greenish, and in pre-penicillin days its viability would have been in serious doubt. This patient recovered full function, the range of movement at the terminal interphalangeal joint being only slightly limited.

The reason for the comparative failure of treatment in 4 cases is not clear. Penicillin was administered soon after symptoms appeared. They were all streptococcal infections, but 2 other cases which were likewise streptococcal obtained full function. These patients, however, were all over 55 years of age, and the difficulty of rehabilitating the patient of this age after a finger injury may explain the poor result.

On general grounds it is felt that larger doses might give still better results, and that the duration of the course might possibly be shortened. Whether larger doses of penicillin will eliminate some of the failures is being made the subject of a further study.

The fact that 10 of the cases treated last year were secondarily infected sheaths serves once more to emphasise the importance of so-called minor sepsis of the fingers. Current studies of pulp infections of the finger in this hospital have shown that systemic penicillin reduces the incidence of complications. The increasing use of penicillin in septic conditions of the fingers should reduce the incidence of secondary tendon-sheath infections, which now must be regarded as largely preventable.

SUMMARY

The results of treating 13 consecutive cases of acute suppurative tenosynovitis of the finger with intramuscular penicillin during 1946 are reported. These results are contrasted with those obtained in an equal number of randomly selected cases treated without penicillin in 1943.

"to cure sometimes, to relieve often, and to comfort always" (Withington 1945). The second responsibility of the universities towards physic—which be it remembered was one of the three faculties of the medieval universities—is to see to it that the medical graduates are in truth members of a learned profession. It is said that, on degree days, the great President Eliot of Harvard always addressed the graduands in the following formula: "Gentlemen, today I welcome you to the great company of educated men." It may be true that his audience always contained a goodly proportion of young men whose intellectual activities were shortly to be displayed in the affairs of the stock market. But the message was clear, and it is this message that we as doctors want from the universities. The student of medicine, just as much as every other undergraduate, needs the education which only a university can give—that integration of the manifold aspects of knowledge and experience which teaches the art of living.

Medicine must therefore remain within the university societies of scholars and students, not only as a means of preserving and enhancing its intellectual traditions but in order that as one form of liberal learning it may make its own contribution to the common pool of university scholarship.

From time to time it has been suggested that the scientific and intellectual aims of medicine would be best served by the creation in each university of an honours school to provide for the handful of brilliant students who are to be found in every year. In another version of the same theme it is suggested that one complete university medical school might be set aside for this purpose. At first glance the idea is most attractive. But I am one of those who regard the deliberate creation of an élite within the profession as fraught with grave danger to the standards of medicine. There are two main objections to such a policy. First, it would perpetuate the false disjunction between the practical man and the scientific doctor of which I have already spoken, and the profession as a whole would soon cease to merit the titles of scientific and learned. Secondly, under the spell of the present trend in the teaching of medicine, an honours school would merely provide an opportunity for the presentation of an additional mass of factual information. No; the mark of a learned profession is that it sets the ideal of scholarship as the common goal of all its members. In medicine we must stand or fall on our corporate traditions and aims.

THE UNIVERSITY HOSPITAL

So far I have dealt with the theme of medicine in its university setting in broad outline only. But we have to remind ourselves that, during three critical years, the student of medicine spends a large part of his working day in a *teaching hospital*. Here for the first time he comes under the full influence of the humanitarian traditions which give him a sense of vocation. But the hospital is also an institution in which the study and practice of handicraft tends to dominate the scene. The student is now called on to become a man of action, and he is taught the important lesson that this is one of the attributes of the "good doctor." Such a background is an appropriate setting for an education in the art of medicine. It is not surprising however that the atmosphere of the teaching hospital tends to be either intellectually neutral or is at times strongly tinged with anti-intellectualism. But the essential scholarship of medicine need not wither away in such an environment if clinical teachers are selected for the quality of their learning. How can this be ensured?

Under the traditional hospital system of Great Britain the influence of the universities on the intellectual standards of clinical teaching has, with notable exceptions, always been indirect and often negligible. Nearly fifty years have elapsed since the first true university was established in an English-speaking country. *may recall* the words of William Osler on this mom event: "The opening of the Johns Hopkins H in 1889 marked a new departure in medical edu in the United States of America. It was not the h itself . . . it was not the men . . . it was the organisa We *still* await the advent of a university hospital Great Britain; and by this I mean one in which clinical pattern of staffing as well as the appointment the entire staff is the responsibility of the univ alone. To those of us who have cherished the ideal the university hospital for many years, the mendations of the Goodenough *Committee* in respect brought a sense of deep frustration. The in the report of the "inevitability of gradu does not satisfy our impatience. Nor does the co tion of the governing bodies of the teaching hospi laid down in the New Health Act, where the representation of the university is but a fifth of total members, seem to bring nearer the consumm of our heart's desire.

In Great Britain there is strong opposition to the wh concept of a university hospital, an opposition rar if ever based on first-hand experience of the working the system in other countries. Nevertheless I rema convinced that the *transformation* of the teachi hospitals of Great Britain into true university hospital would do more than any other single act of reform i *medical education to ensure that our* successors w indeed be members of a liberal, scientific, and learn profession.

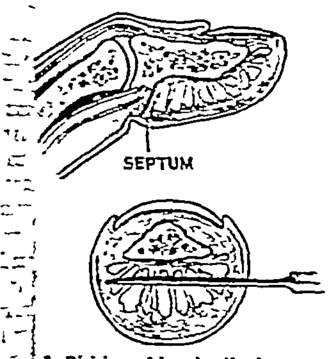
BIRMINGHAM ACCIDENT HOSPITAL

INFECTIONS of the hand following minor *injury* have long been recognised as an important cause of permanent disablement and of serious loss of industrial time. The reduction of this wastage should become possible wit the increased production of penicillin.

Acute suppurative *tenosynovitis is probably* the most damaging of the hand infections, and at this hospital it is seen largely as an industrial complaint. To test the effectiveness of intramuscular penicillin in this condition an investigation was carried out on all the cases treated during 1946 by one of the four surgeons (S. H. H.). The clinical diagnosis was confirmed in each case at operation; 10 of the 13 cases were frankly purulent at operation, but the minimal criterion for *inclusion* was the presence of an excess of clear fluid in the sheath *at operation*. This occurred in 1 case secondary to a pulp infection, and culture subsequently yielded *Staph. aureus*.

In 9 cases there was a history of *minor injury*, and in 8 of these the injury had been incurred in the course of the patient's work. The injuries ranged from a compound fracture of the terminal phalanx to apparently trivial re was, however, no significant difference in either the bidity time or the development of complications in two classes. One case in each class developed itis. No clinical difference was noted in the healing with and without penicillin.



2—Division of longitudinal septa.

SUSPECTED BONY FELON

This group. into which 20 of our cases fell. is not adequately defined or appreciated by English writers. It is essentially a clinical diagnosis; for, though most infected pulp spaces show diffuse osteoporosis of the terminal phalanx within a few days, radio- hical evidence of bony erosion is not apparent for 10–12 s, or perhaps several weeks, after the primary infection. this category bony infection is already present but lographic evidence lacking. If the correct treatment not pursued before radiological confirmation of bony osis, much valuable time is lost and an easily con- llable infection progresses to disastrous destruction. e factors arousing clinical suspicion of an established e infection without demonstrable radiographic dence are (1) length of history, (2) amount of tissue osis, and (3) previous inadequate incision.

(1) If a sinus or an open wound, spontaneous or post- onal, has been discharging for a week or ten days shows no unmistakable evidence of healing, it is emely likely that there is an underlying bone infection. bead of thin seropus appearing on light expression is pecially significant.

(2) The amount of tissue necrosis is clinically shown y the club-like swelling of the pulp space, a bogginess hich has replaced the early tenseness, or a threatened metimes obvious) central sinus, especially towards the p. This last sign, described by Klapp (cited by Iselin 40) is most reliable. The spread of infection to the cumungual region or to the distal interphalangeal joint pathognomonic. At operation massive sloughing of the ft tissue is important evidence. Investigation of e phalangeal periosteum at the time of operation is nadvisable, since this may cause a breach in the reviously intact periosteum and introduce organisms to the unin- cted bone.

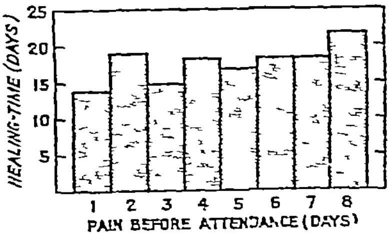


Fig. 3—Duration of pain and average time of healing in simple felon.

(3) If the finger has been treated by inadequate incision—e.g., idline and short lateral incisions—without giving adequate drainage and has continued to be tense and painful after a short temporary relief, an osteitis is an almost inevitable sequel. Six of the cases in our series demonstrated this point. The character or position of the original pain (cf. Iselin 1940, Cutler 1942) seems to be of no importance, and in two cases of severe systemic disease (one case of mitral stenosis and one case of diabetes) the finger healed within the average time. A warning is necessary about the common phlyctenular type of infection. These cases are worthy of investigation under adequate anæsthesia and should not merely be nicked under local ethyl chloride. Too often a narrow track leads into the pulp space proper and, after temporary relief following the superficial incision, an acute felon develops.

Controls.—No controls were used, because the diagnosis of this category of felon is one of suspicion only and the number of cases (20) was insufficient to be reliable as statistical evidence.

Treatment and Results.—The principles of surgical treatment are the same as for the simple felon: adequate drainage of the soft parts, avoidance of secondary infection, and rest. To these must be added antibiotic therapy. The sulphonamides, in our opinion, are of minimal value, since the usual organism is the *Staph. aureus* and their action is vitiated by the ever-present pus or sloughs. It is at this stage, before the formation of sequestra or massive bony necrosis, that penicillin is so valuable. The dosage of 100,000 units b.d. has in our experience proved adequate, provided it is exhibited long enough—i.e., 10–21 days, according to the progress of the disease. By this means minimal damage is incurred by the phalanx, the bone is quickly re-formed, and the finger is healed comparatively soon, usually within four weeks. Serial radiograms taken at intervals of 3 or 4 days would often show "mouse-nibbling" of the osteoporotic phalanx; but, in place of the unremitting progress of the disease to subtotal or total necrosis of the phalanx, the erosion is halted and the bone recalcified in a few weeks, usually without any demonstrable sequestra. Radiotherapy as advocated by Baker (1947) was not used, but it should be worth while in the treatment of bone infection due to organisms of low penicillin-sensitivity.

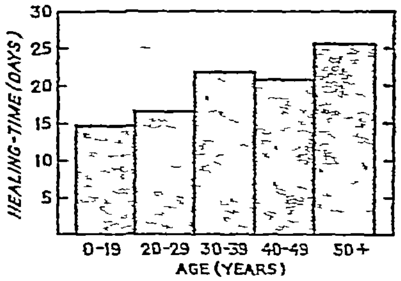

Fig. 4—Age of patient and average time of healing in simple felon.

It is difficult to gather significant statistical evidence for the value of surgery with penicillin in this group of early bone infection: but since the two groups of simple felon and suspected felon were clearly distinguished and treated as such in our cases, well-established destructive osteitis has been eliminated.

ESTABLISHED BONY FELON

At any large hand clinic some cases must appear with well-established bone infection demonstrable by radiography. The diagnosis is never in doubt: the decalcified osteoporotic phalanx shows focal necrosis, most commonly on the palmar surface of the tip of the phalanx or at the waist of the bone. The former seems to be the more self-limiting type of infection, though it may spread proximally and give a subtotal or total necrosis of the whole bone. The central diaphyseal infection—i.e., at the waist of the bone—tends to spread more rapidly along the medulla and rarely terminates without sequestrating the whole of the diaphysis. In both types the narrow rim of the epiphysis usually survives. The osteoporosis which is constantly seen before the destructive osteitis is probably due to the hyperæmia resulting from infection of the soft tissue. The tendency for the erosion to start distally seems to support the theory of lymphatic spread rather than ischæmic necrosis due to thrombosis of the diaphyseal arterial supply as propounded by Kanavel (1925). If the latter were true, the radiographical appearance should be one of increased density of sequestra as contrasted with the more osteoporotic surrounding viable bone. We never saw this.

Controls.—We reviewed 30 cases treated, before this series, conservatively without intramuscular penicillin and

The results indicate a reversal of the prognosis of acute tendon-sheath infections in that 8 of the penicillin-treated cases proceeded to full functional recovery, whereas 9 of the "untreated" cases required amputation.

The reduction in the duration of disability is striking.

The use of systemic penicillin in conjunction with minimal surgery is advocated in the treatment of acute suppurative tenosynovitis of the finger.

We wish to thank Dr. J. R. Squire, director of the Medical Research Council Industrial Medicine Research Unit, Birmingham Accident Hospital, for his advice on the preparation of this report, and Mr. W. Gissane, clinical director at the hospital, for permission to use the case-records.

PENICILLIN IN PULP-SPACE INFECTIONS OF THE FINGER

H. BOLTON M.B. Manc.
B. N. CATCHPOLE M.B. Manc.
R. P. JEPSON M.B. Manc.

From the Surgical Professorial Unit, Royal Infirmary, Manchester

THE importance of organised early and adequate care of the infected finger has been repeatedly emphasised by many authors (Kanavel 1925, Bunnell 1944, Iselin 1940, and Koch 1937); but little has been published since the advent and general use of penicillin.

To assess the value of penicillin in pulp-space infection we studied 100 consecutive cases in the outpatient hand clinic of a general hospital. Personnel and methods were standardised, and all incisions were made by either B. N. C. or H. B. The cases fell naturally into three groups and are analysed separately: early simple felon (69 cases), suspected bony felon (20 cases), and established bony felon (11 cases).

SIMPLE FELON

Diagnosis.—The diagnosis is rarely in doubt: a throbbing pain has been present for a few hours or some weeks; and the affected pulp space is tender and swollen and shows the cardinal sign, a loss of the normal pulp elasticity to the examiner's touch.

Treatment.—We have no experience of the conservative treatments using short-wave diathermy or plaster-of-paris, with or without penicillin, since we believe them to be at variance with established surgical principles. The absence of published work advocating their adoption is noteworthy. The treatment is incision, preferably under a tourniquet with adequate general anæsthesia. Of the incisions generally used the crocodile-mouth type, looping from side to side over the tip of the pulp, may lead to severe skin sloughing and in any event a poor tactile surface. Weiner's (1940) posterior approach was not used by us but seems worthy of trial. The bilateral incision was unsatisfactory in our hands, some fingers having to be reopened later because of early pocketing.

The standard incision used by us was the lateral "hockey-stick," with the tip of the J approaching to within 3 mm. of the nail-skin junction, and the proximal limb ending some 5 mm. short of the ventral flexor crease, the septa of the pulp being divided with a narrow scalpel across to the subcutaneous tissues of the opposite side (fig. 1). This allows adequate decompression of the pulp space, brings into view, for division, all the longitudinal septa across to the other side of the pulp (fig. 2), and leaves a satisfactory cosmetic and tactile surface postoperatively. No attempt was made to excise the infected soft tissues as described by Iselin (1940). The heavy corrugated rubber drain, with its tendency to pressure necrosis, was discarded in favour of a thin of rubber glove, which was left in for 12–18 hours.

The need to avoid soaks, moist dressings, and septic baths in the postoperative period has emphasised by Bailey (1941). It is surprising to see methods being advised by other authors (Edwards Macey 1940). This treatment encourages seco *infection and leads to swollen œdematous* exaggerating the normal inflammatory œdema interfering with the drainage of the part. It is difficult to persuade patients against soaking, since are impressed by the amount of pus exuding at each The soaks are, however, the cause of the pus, not the

Our routine was infrequent (every 3 or 4 days) d of a thin layer of soft-paraffin gauze over a light of penicillin powder surrounded by a dry gauze d *This causes no pain on removal, discourages* seco infection, and has sufficient absorptive power f small amount of exudate. A splint for a day or so a triangular bandage sling were used according to amount of local reaction. Short-wave diathermy adopted postoperatively as a form of dry heat gives at least a psychological fillip to the patient. value is difficult to assess but at least it does no and it establishes contact between the patient and physiotherapist which can be maintained in the last days for the supervision of finger movements.

The average time from first attendance at the clin to discharge with a healed epithelised finger was 17 day *the minimum was 7 days and the maximum* 6 wee

In an effort to analyse the factors involved in prolonging this morbidity, the following variants were studied.

Bacteriology.—Of the 100 cases of all types of felon, simple, suspected, and established, 99 grew a pure culture of *Staph. aureus*, coagulase-positive and penicillin-sensitive. The unique exception was a finger, already incised before the patient began to attend the clin which grew a *Strep. hæmolyticus.* The virulence of t organism could not be estimated, and the tissue resistan of different patients was unknown.

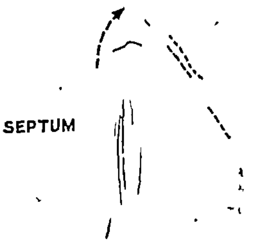

Fig. 1—Hockey-stick incisio

Duration of Pain before Incision.—This is summari in fig. 3. Other factors being equal, the duration of was of no prognostic importance. It seems that hyperacute infection, with its excessive pain and lik complicating sequelæ, brings the patient early for tr ment. The milder infection, with its more tolera pain, is borne longer by the patient, and these t variables cancel themselves out.

Finger Involved.—The thumb and forefinger were t most commonly affected; but there was no signific difference in time of healing, whichever digit was involv

Ætiology.—A third of the patients could give no h of the cause of the infection. The rest accused pinpric traumatic blisters, fishbones, &c. No cases of hum bite were seen. There was no appreciable difference in the healing-time in these groups.

Age of Patient.—As one might have suspected, t young healed more quickly than the old. The difference, which was not great, is summarised in fig. 4.

Penicillin Therapy.—It was hoped that a three-da course of penicillin would reduce the morbidity period, and alternative cases were selected without discrimination for such treatment. *The dosage was 100,000 units by* intramuscular injection twice a day in the outpatient clinic. This is probably a low dosage, but economy, the difficulties of outpatient therapy, and the lack of a *satisfactory oily preparation made this unavoidable.*

ected out with scalpel and scissors. Drainage was ntained by packing the wound open for 48 hours with e impregnated in the first three groups with penicillin lm 100 units per g., and in the fourth group with ile soft paraffin.

he criterion of cure in every case was a dry epithelised nd, and every patient was discharged to full-time loyment with complete functional recovery.

group I 40 patients were treated as described above were given intramuscular penicillin in oil and wax 250,000 units daily until the wound discharge serosanguineous. The local dressing of penicillin m on sterile gauze was changed every second day l wound discharge was serosanguineous, and thereafter gauze until healed. In this group wound swabs were n at operation, and the type and penicillin-sensitivity e infecting organism determined. Since the organisms almost invariably penicillin-sensitive *Staph. aureus* on only two occasions penicillin-sensitive *Strep. lyticus,* wound swabs were not taken in subsequent ps.

ood-penicillin levels 24 hours after injection were mined in this group, and in no case was the level tantly bacteriostatic. No attempt was made to attain nstant bacteriostatic level in the blood by spaced ctions, because the local reaction at the site of tion caused patients to refuse further injections. main reason for not recommending spaced injections the realisation, at this point in the investigation, those who refused further injections healed just as ly as those who continued with the injections.

e treatment of the 47 cases in group II was exactly group I, except that the dosage of penicillin in oil beeswax was reduced to 125,000 units daily until wound discharge was serosanguineous.

roup III consisted of 61 cases treated with intra-cular sodium-penicillin aqueous solution 200,000 s daily until the wound discharge was serosanguine-. Local dressings, &c., were exactly the same as in ups I and II.

n group IV, consisting of 112 cases, all patients had same operative treatment as in the previous three ups, but no penicillin was administered parenterally used as a local dressing. After operation, a sterile t paraffin gauze pack was inserted into the wound changed every second day, until the wound discharge serosanguineous. Thereafter the local dressing was ile gauze.

RESULTS

he accompanying table shows that there is no reduction of the length of disability when acute infections of hand are treated with penicillin. This is due to the t that the infections are localised and pus is present ore the patient reports to his doctor. Only 7 cases e seen early enough to justify an attempt to abort infection with parenteral penicillin. In only 3 of e 7 was the attempt successful: these were subcutane- infections of the dorsal and palmar aspects of the gers The 4 failures were in 3 pulp infections and 1 bcutaneous abscess.

It is impossible to abort pulp infections with parenteral enicillin. The tension in a pulp infection interferes with e blood-supply of the pulp; and, unless the tension relieved by incision, thrombosis takes place in the lp anastomosis, with tissue necrosis and subsequent s formation. In 4 cases of pulp infection where no s was found at operation I was confident they would ve progressed to pus formation had the tension in the lp not been relieved by early incision. The healing ter tension was relieved was rapid, and the patient was ischarged to full-time employment in about 4–6 days.

The best treatment for threatening pulp infections is rly lateral incisions; no time should be wasted in omenting the finger. The benefit derived from relief of tension in the enclosed compartment of the pulp space far outweighs the harm of operation trauma. In the 4 cases mentioned there was no dissemination of infection.

RESULTS OF DIFFERENT TREATMENTS OF ACUTE HAND INFECTIONS

* For the different treatments of the groups see text.

The effect of parenteral penicillin in the successful cases was much lessening of the pain in 24 hours, the patient being able to sleep the night after the first injection. The condition entirely settled after the third daily injection, the total dosage of penicillin in oil and beeswax being 750,000 units in each case.

In the unsuccessful cases there was less amelioration of pain and swelling, and after three days' treatment, though the throbbing pain had subsided to a dull ache with an occasional stab of pain on movement, it was evident from tenderness to palpation and softening at the centre of the indurated area that pus had formed and that its evacuation was essential. All failures had a total of 750,000 units of penicillin in oil and beeswax each, given in three days.

Postoperative Penicillin.—No beneficial effects were noted from the parenteral administration of penicillin postoperatively. In group IV there was the same relief of pain and diminution of swelling postoperatively as in group I. Lymphangitis and lymphadenitis settled almost as rapidly in group IV as in group I. In no case in group IV was there an extension of infection or abscess formation due to suppuration of an enlarged gland. A patient treated for an acute infection of the hand, first in group I and again in group IV, thanked me for not giving him injections for his second pulp infection. He said that in the first instance the cure was as bad as the disease, for he had a large local reaction at the site of injection of penicillin in oil and beeswax.

Penicillin in Oil and Beeswax.—The adverse effects of penicillin in oil and beeswax were a major concern in the treatment of patients. Many patients refused further injections after a local reaction to penicillin in oil and beeswax at the site of a previous injection. The reactions to penicillin in oil and beeswax were of two main types, general and local. In this series there were 3 general and 8 local reactions.

All the general reactions were of an urticarial type with a macular rash all over the body. The cutaneous manifestations were preceded by vertigo and shivering, and anorexia and a feeling of nausea persisted 24 hours after the first appearance of urticaria. On administration of 1 in 1000 adrenaline and cessation of penicillin the patient recovered and the rash faded rapidly. Subsewith soaks, local dressings, short-wave diathermy, &c., and found the healing-time to average 14 weeks.

Treatment and Results.—The treatment of the established case of osteitis has been the subject of considerable debate. Kanavel and König (cited by Iselin 1940) have advised early and radical excision of the affected bone, even before sequestra become defined. The distal part of the phalanx is resected with reflexion of the periosteum towards the base. This attempt to limit and eradicate osteitis by surgical attack has, in our experience, been disastrous. As Koch (1937) points out:

> "Unless sequestration has actually taken place, one cannot determine by inspection, even in a bloodless field, where necrosis of the bone ends, where the protective wall of inflammatory reaction begins."

In three cases previous to and not included in this series we attempted to shorten the course of the disease by incision into the pulp space and removal of the affected part of the phalanx proximal to the lesion visible in the radiogram. We were grossly mistaken. The pulp tissue, already deficient from the soft-tissue necrosis, is left unsupported after the removal of the distal half of the phalanx, with the result that the palmar skin becomes apposed to the nailbed. A course of penicillin had been given for 48 hours preoperatively and was maintained for a week postoperatively. This controlled the infection, and serial radiograms showed no further focus in the remaining proximal segment, though crescents of cortex detached from the removed phalanx could be seen adherent to the underlying nailbed. The pulp spaces, however, showed a remarkable reluctance to form granulation tissue and remained collapsed and empty sacs, which filled from time to time with a few beads of pus. *These three cases took an average of 5 months* to heal and even then were left with poor pulp pads and deficient tactile sensation.

After this experience we adopted a more conservative attitude. Adequate drainage of the pulp space was established by a hockey-stick incision and secondary infection avoided by infrequent dressings on the line of the technique described above. A long course of penicillin was instituted, 100,000 units b.d. intramuscularly for at least 2 weeks. Serial radiograms were taken at intervals of 5–7 days and the course of the bone necrosis was followed. When, and only when, sequestra became clearly demarcated was the wound, if necessary, reopened and the necrotic detached fragments removed. Often no sequestrectomy was required, the loose necrotic bone being absorbed by the invading granulation tissue. The results were most encouraging; every finger so treated healed within 8 weeks; and, though the pulp pad was usually thin, the finger was both *cosmetically and functionally adequate.* Even if an arthritis of the distal interphalangeal joint had already developed, treatment on these lines was still maintained. Our two cases with a subtotal terminal phalangeal osteitis and purulent arthritis of the distal interphalangeal joint recovered 50% of the joint movement and an adequate pulp pad. If a paronychia runs concurrently with the bony felon, this will need an additional dorsal incision. No other complications were seen in this series.

SUMMARY

Pulp-space infections are divided into (1) simple felons, (2) suspected bony felons, and (3) established bony felons.

Simple felons and suspected bony felons were incised with a lateral hockey-stick incision, and all the longitudinal septa of the pulp were divided. The pulp space was then drained. Soaks, moist dressings, and antiseptic baths were avoided. Instead, a light film of penicillin powder was applied, covered with a thin layer of soft-paraffin gauze and a dry gauze dressing.

The average time of recovery for simple felons was 17 days—minimum 7 days, maximum 6 weeks.

Of 100 cases of all three types of felon 99 grew a culture of *Staph. aureus.* The remaining finger, had previously been incised, grew *Strep. hæmol*

Alternate cases of the 69 simple felons were treated with intramuscular penicillin 100,000 units daily for three days, without any significant effect.

In suspected bony felon, before the develop *radiographically* visible lesions of the bone, intram penicillin 100,000 units twice daily was most val if administered long enough—i.e., for 10–21 days.

In established bony felon the removal of pulp necrotic bone proved disastrous. Adequate and infrequent dressing, as already described, co with intramuscular penicillin 100,000 units twice for at least 2 weeks, gave most encouraging Usually no late sequestrectomy was needed, the n bone having been absorbed. Every finger so t healed in 8 weeks.

Our thanks are due to Prof. A. M. Boyd, under supervision this study has been made, and to the radiol pathological, and physiotherapy departments of Manchester Royal Infirmary for their technical assistan

USE OF PENICILLIN IN ACUTE INFECTIONS OF THE HAND

A. L. WEBSTER
M.B. St. And.
TEMPORARY CLINICAL ASSISTANT, SURGICAL OUTPATIE DEPARTMENT, ROYAL INFIRMARY, DUNDEE

It is claimed that the administration of penicillin all types of acute infections of the hand reduces t length of disability and the amount of perman disablement and improves *the result* from an æsthe viewpoint. Consequently an account of my experien with penicillin in such cases among outpatients of Dund Royal Infirmary may be of interest.

A series of 260 unselected cases of acute infections the hand were treated in the outpatient department four different methods. The cases were mostly p infections, subcutaneous abscesses, onychias, and p onychias, there being only 16 cases of infected palmar thenar space. All tendon-sheath infections were admitt to the wards and are not included in this series. The c when first seen, were usually sufficiently advanced f pus to have formed; only 7 were seen before pus h formed. Most were localised, but a fair percentage h lymphangitis and lymphadenitis.

To assess the results a comparison is made with 2 cases of acute hand infections from past records of t surgical outpatient department. These "*control*" ca were operated on by various doctors and the treatment as proportionately varied.

TREATMENT

The cases are divided into four main groups, which, however, do not contain equal numbers of cases, since the change of treatment was not governed by the number *of cases treated but by the results obtained,* the patient's comfort and welfare being the first consideration. All operations were performed under gas-oxygen and 'Trilene' anæsthesia, and in every case a bloodless field was obtained by the use of a sphygmomanometer cuff *at 200 mm. Hg. At operation* adequate incisions were *made to allow free escape of pus,* and all sloughs were ously treated cases of amœbiasis readmitted for review ot included. Under the heading "chronic intestinal asis" are included cases presenting with symptoms than acute diarrhœa. "Clinical dysentery" includes with blood and mucus but no amœbæ found, and stool re and sigmoidoscopy negative.

vergent figures have appeared from time to time the relative incidence of bacillary and amœbic tery. Manson-Bahr (1943) attributes this incon- cy to two factors: the faulty identification of mœba histolytica (E.H.); and the incomplete bacterio- al examination of stools. If, however, the diagnosis œbic dysentery is confined to those cases in which ely motile amœbæ containing red blood-cells are d in the stools, and if, also, routine stool culture and idoscopy are carried out in all cases of diarrhœa hich the slightest doubt about the diagnosis exists, pears that these two factors do not offer an adequate nation. It was on such criteria that the figures above were obtained. I suggest a more likely for the gross variations in statistics: that the tion of the two diseases depends entirely on the nce or absence of any major epidemic of bacillary tery during the period under review. In Ceylon g the year there was no epidemic of bacillary tery in the R.A.F., a fact largely attributable to bviation of the fly menace coincident with the duction of D.D.T. and the high standard of hygiene the services throughout the island.

se figures are therefore submitted as an accurate arison of endemic types of dysentery in Ceylon. such they reveal a startlingly high percentage of dysentery, higher than recorded by other writers the war. Leishman and Kelsall (1944) found that in 4 of all diarrhœa patients admitted to hos- was amœbic in origin, and Marriott (1945) showed incidence of amœbiasis in such cases. Payne) found that 56% of all cases of dysentery admitted base hospital were due to amœbiasis. However, Colonial Office Reports (1929) (quoted by Manson- r 1943) give the incidence of amœbic dysentery 3% in a survey of 5900 cases of dysentery in the population of Ceylon.

e problem of amœbiasis, then, is enormous and be simply summarised thus: that every second ent admitted to hospital with diarrhœa has amœbic entery. When this is viewed in conjunction with the essing articles on the failure of therapy in chronic biasis (Lamb and Royston 1945, Morton 1945) becomes alarming, and the importance of the correct y diagnosis and efficient treatment of amœbiasis omes the all-important responsibility of every doctor reas.

ACTION OF SULPHONAMIDES

The efficacy of sulphonamides in the treatment of illary dysentery is so well established that it has come the custom in many hospitals overseas to use se drugs as a diagnostic test in cases of dysentery on e assumption that cases which respond rapidly are illary in origin, whereas those in which the symptoms ist are probably amœbic. That this axiom might be llacious was first suspected in the following cases.

Case 1.—A leading aircraftman was admitted with acute rhœa with blood and mucus. The report on the first ol sent for examination read "Typical bacillary exudate. o E.H. seen." Treatment with sulphapyridine was started receipt of the report in the ward. Next day he had proved, having passed only 3 stools in the twenty hours er treatment began as against 12 in the previous twenty- r hours. A stool submitted on this day contained many tive E.H. In view of this apparent paradox the sulpha- ridine was continued and further stools were sent for amination, but thereafter all stools were formed and no E.H. were found. A full course of anti-amœbic treatment was en given. Unfortunately no sigmoidoscopy was done in this case until treatment was completed, when no abnormality was found.

TABLE I—EFFECT OF SULPHONAMIDES IN AMŒBIC DYSENTERY

Case no.	Before treatment: Stools: No. in 24 hrs.	Nature and findings	Blood	Mucus	E.H.	Treatment given	Response to treatment: No. of stools passed each 24 hours after treatment began: 1st	2nd	3rd	4th	5th	Day on which stools examined became negative for E.H.
1	5	Fluid	+	+	++	S-pyr. 22 g.	5	5	2	0	Em	? (+ on 3rd)
2	4	Fluid	+	+	++	S-pyr. 22 g.	4	2	0	0	Em	? (+ on 2nd; no stool available 3rd and 4th)
3*	20	No fæcal matter	+	+	+	S-pyr. 14 g.	4	0	1	Em	..	3rd
4	8	Fluid	+	+	+++	S-pyr. 14 g.	8	4	5	Em	..	? (+ on 4th)
5*	12	No fæcal matter	+	+	+	S-pyr. 22 g.	8	1	0	0	Em	? (no stool available after 2nd)
6	4	Fluid	0	0	+	S-pyr. 15 g.	2	0	0	1	Em	4th
7	6	No fæcal matter	+	+	+	S-dia. 23 g.	6	3	2	Em	..	2nd
8	14	Fluid	–	+	++	S-gua. 70 g.	11	3	1	1	Em	3rd
9†	5	Fluid	–	+	++	S-gua. 100 g.	8	6	4	3	3	4th
10	6	No fæcal matter	+	+	+++	S-pyr. 6 g. S-dia. 15 g.	7	4	4	Em	..	3rd

S-pyr. = sulphapyridine; S-dia. = sulphadiazine; S-gua. = sulphaguanidine, Em = emetine started.

* Sigmoidoscopy before start of emetine therapy showed acute amœbic ulcers.

† This patient normally had his bowels open three times daily.

Case 2.—A sergeant had had, ten days before admission, acute diarrhœa, passing 10–20 stools daily with blood and mucus. Admitted to sick quarters, he was treated with castor oil, with no improvement. He was then given sulphaguanidine 26 g. in two days, at the end of which time his diarrhœa had improved, and he was transferred to hospital for further treatment. During the first twenty-four hours in hospital he passed one formed stool and felt so fit that he resented further investigation; but this one stool contained vegetative E.H., and sigmoidoscopy next day showed many circumscribed submucosal hæmorrhages and a few shallow ulcers.

Case 3.—A leading aircraftman was admitted with diarrhœa of four days' duration. No E.H. was found in the first specimen, and a full course of sulphaguanidine (100 g.) was given. The response was immediate, and stools became normal within forty-eight hours of treatment. Routine sigmoidoscopy at the end of the course showed typical "pin-point" amœbic lesions.

These observations suggested that the sulphonamides at least mask the symptoms of acute amœbiasis and may indeed have had an amœbicidal action. It was therefore decided to give a short preliminary course of various sulphonamides in proved cases of acute amœbic dysentery and to observe the response. The results of the 10 cases so treated are summarised in table I.

It was clear from these cases that, with one exception (case 4) whose condition deteriorated during treatment, a well-marked clinical improvement took place with a diminution of the number, and a return to normal in the nature, of the stools. Of the 9 cases that responded, 6 (nos. 3, 6, 7, 8, 9, and 10) showed a negative stool from the second to fourth days, in 2 (nos. 2 and 5) no stools were available after the second day, and in 1 (no. 1) *quent administration of sodium penicillin in aqua to* 1 patient did not evoke either a local or a general reaction.

Minimal local reactions developed in most patients who received penicillin in oil and beeswax. There were usually slight erythema and deep induration round the needle wound. The degree of reaction in the 8 cases noted varied from a minimal area of erythema and induration of 3 in. by 2 in. to a maximal area of the whole arm and hand swollen and œdematous. The main subjective symptoms were a burning sensation and intense itching. One patient had a local reaction in both arms simultaneously, and the incapacity was such that she had to be dressed and fed. The reaction gradually settles in 8–11 days *on cessation of penicillin.*

End-results.—The end-results were similar in all groups. The cases with bone necrosis, necessitating sequestrectomy, occurred in all groups, and occurred only in cases which had been sent for treatment at a late stage, often after one or two attempts had been made to open the infected area under local anæsthesia. Before reporting, many of these patients had had a fairly intensive course of penicillin following the inadequate *incision in the hope that chemotherapy might mitigate* the consequences of inadequate surgery.

Modified Treatment.—Besides the present series of 260 cases, 16 patients were treated by modifying the method of local application of penicillin. In 10 cases of subcutaneous abscess 1 ml. of sodium penicillin in aqua, 200,000 units per ml., was injected into the tissues round the incision made for the evacuation of pus. The postoperative pain was severe and persisted four hours after operation, necessitating sedative treatment. Healing was not accelerated by such treatment. An attempt was made to clear up chronic paronychias by infiltration of the nail-fold with sodium penicillin in aqua, 20,000 units per ml. In only 1 case was this attempted without an anæsthetic, but the pain caused was so great that the operation had to be abandoned after 0·25 ml. had been infiltrated. In 5 cases 1 ml. of sodium penicillin in aqua, *20,000 units per ml.*, was injected into the nail-fold under general anæsthesia: 3 cases cleared and the condition was cured in five days; and 2 cases came to operation for removal of the nail loosened and undermined by pus. The postoperative pain was severe and lasted an average of twelve hours, the patient being unable to sleep the night following operation without a sedative.

The principle of the Bunyan bag was applied to the dressing *of large superficial infections of the fingers.* After incision and drainage, a sterile rubber finger-cot was rolled over the finger and fixed with adhesive to the base of the finger, and 2 ml. of sodium penicillin in aqua, 10,000 units per ml., was *introduced* under the adhesive band, with a syringe and needle, to flood the finger-cot. A gauze dressing was bandaged lightly over the rubber finger-cot and left undisturbed for two days. The wound, on removal of the dressing, was clean and *healing, though the skin round it was macerated. Healing* took place rapidly thereafter with sterile gauze dressings. This method of dressing caused no pain and had the advantage of causing a slight passive hyperæmia of the part, as in Bier's method of treatment of acute inflammation.

Penicillin-sulphathiazole Powder.—The use of penicillin-sulphathiazole powder as a postoperative dressing is to be condemned. The powder and wound exudate form a combination as hard as stone, which effectively cements over the *incision made for the evacuation of pus.* Often this cast of wound exudate and penicillin-sulphathiazole powder had to be picked off the finger with forceps to allow evacuation of the pus trapped under it.

CONCLUSIONS

Penicillin is useful in the treatment of all acute infections of the hand *except pulp infections*, if they are seen and treated before pus has formed. After the formation of pus, and when there is necrosis of tissue and formation, the best treatment is adequate i.e., adequate incisions, with removal of all dissection, in a bloodless field under general

Penicillin in aqueous solution given either tively or postoperatively does not confer any benefit, except perhaps in cases with lymphangitis lymphadenitis.

Penicillin in oil and beeswax often increases the suffering.

As a local postoperative dressing, sterile soft gauze is as good as any, and better than most of It maintains drainage far better than does a ru and never obstructs drainage, since it can easily be from the wound. Since it does not adhere to the dressings are less painful; and when granula present they sustain no trauma at the time of

SUMMARY

A series of 148 cases of acute infections of the treated with local and parenteral penicillin by different methods is reviewed and compared wi cases treated with sterile dressings without

An attempt was made to abort 7 cases of acute tions of the hand with parenteral penicillin; in o cases was it successful.

No benefit was obtained from postoperative parent penicillin.

General or local reactions to penicillin in oil beeswax were troublesome in 8 out of 87 cases.

The results obtained in 16 cases of acute the hand treated by *local injection* of sodium p in aqueous solution are described.

A method whereby the principle of the B is adopted for the treatment of large su infections of the finger proved useful.

Penicillin-sulphathiazole powder as a postop dressing for acute infections of the hand is cond

I wish to thank Prof. R. C. Alexander and Dr. H. J. Gibson, *medical superintendent*, for permission to pu this article; Mr. W. G. Campbell for his help and encou ment in preparing this paper; and the honorary st surgical outpatient department, Dundee Royal Infirm for permission to treat their cases.

AMŒBIASIS IN CEYLON

THOMAS PARKINSON
M.D. Lond., M.R.C.P.
MEDICAL CHIEF ASSISTANT, ST. BARTHOLOMEW'S HOSPIT
LONDON; LATELY SQUADRON-LEADER R.A.F.V.R.

THE material for this paper has been drawn from year's experience in a R.A.F. mobile field hospital Ceylon between October, 1944, and September, 19 No cases outside the year have been included in t statistics, but 2 others are reported to demonstr clinical observations. The object of the paper is mai to show how high is the incidence of amœbiasis Ceylon, to point out a common misconception in management of undiagnosed diarrhœa, to suggest addition to the routine treatment of amœbiasis, and discuss the clinical picture of amœbic hepatitis.

INCIDENCE

The total number of admissions to the medical w of this hospital during the year was 635; of th 191 cases were classified as "dysenteric disorders and are analysed *as follows*:

Amœbic group		97	(50·8%)
Primary acute amœbic dysentery	62		
Acute relapse of amœbic dysentery	9		
Chronic intestinal amœbiasis	15		
Amœbic hepatitis	9		
Liver abscess	2		
Bacillary dysentery		15	(7·9%)
Clinical dysentery		14	(7·3%)
Non-specific diarrhœa		63	(32·9%)
Lambliasis		2	(1·1%)

ndemic dysentery, the practice of treating undiagnosed rhœa with these drugs should be condemned.

urther, there is some evidence that sulphonamides y be potent therapeutic agents in the treatment of œbiasis. When they are used in conjunction with tine, the immediate results are rapid, and no relapses e been experienced.

mœbic hepatitis presents a definite clinical picture may occur in the absence of a previous history of entery. Negative stool examination and a low leucoe-count do not rule out the diagnosis, and response metine is good.

wish to thank the Director-General of Medical Services, F., for permission to publish this paper Sister E. A. dland, P.M. R.A.F. N.S., for her coöperation in the supern of the cases, and Sergeant N. H. House and Leading raftman H. Gott, laboratory assistants, for their untiring in the examination of specimens.

CONGENITAL FUNNEL CHEST

H. S K. SAINSBURY
M R.C.S.
ASSISTANT SCHOOL MEDICAL OFFICER, BIRMINGHAM
EDUCATIONAL DEPARTMENT

NNEL chest was first described by Eggel in 1870 st (1887) recorded the condition in brothers and rs, Grünenthal (1888) in brothers, sisters, and an t, Smith (1886) in mother and daughter, and Vetlesen 6) in father and son. Thus it came to be regarded familial.

Peiper (1922) and Snyder and Curtis (1934) noted funnel st among three generations, and Klemperer (1888) ong four, suggesting that it can appear as a dominant racter. In the following cases there seemed no doubt t it was inherited as a dominant character.

A boy, aged 12 years, was noted on routine medical inspecn at school to have funnel chest Subsequently his ther and his younger brother were found to have an ntical condition All four brothers had had whooping gh when children but no other illnesses.

The mother said that, when she was a girl, both her other and her grandmother told her that they had a similar st, and she remembered seeing the same defect in her unger brother. She discovered the funnel chest in her own ldren shortly after their birth.

The condition in the three women was known to the late mily doctor, but no personal record of his observations uld be traced

The mother made inquiries among the three other branches the family, but the negative results were not necessarily ved on medical examination

The females through whom the defect has been transmitted serve definite familial features They are tall and spare hey are healthy and long lived There was no intermarriage blood relations

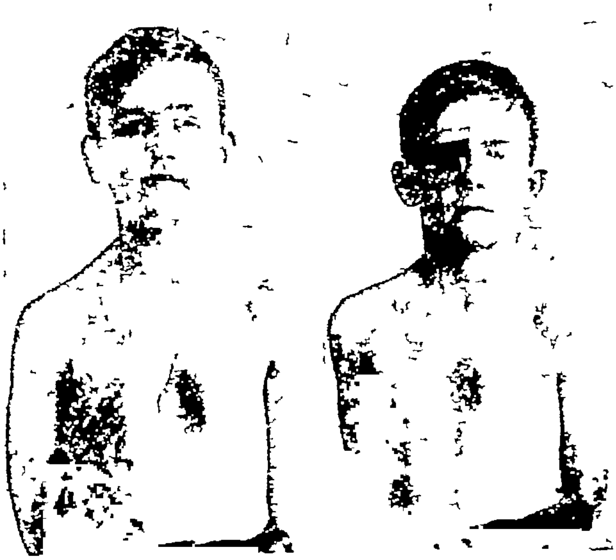

Fig. 2—Funnel chest in two brothers, whose mother also had funnel chest (see fig. 1).

The family pedigree is shown in fig. 1. The earlier details were checked from entries recorded on the flyleaf of the family Bible salvaged from the air-raid shelter.

On examination the two boys and their mother showed no other abnormality of skeleton, breast, musculature of the thoracic wall, hand, or arm. The deformity was that of a funnel chest. There was no clinical evidence of foramen or fissure of the sternum, but radiograms could not be obtained. The type and degree of deformity is shown in fig 2.

DISCUSSION

Funnel chest is by no means uncommon (among 1120 inspections 4 cases of similar severity were observed), but the incidence seems to vary in different districts.

The family history is usually difficult to investigate for the following reasons:

(1) Funnel chest is seldom known of outside the immediate family circle, being normally hidden by clothing.

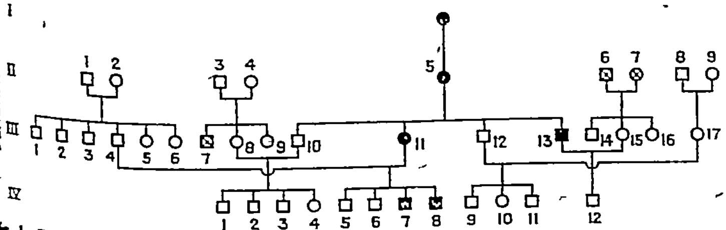
(2) It causes no symptoms and consequently is only met with casually. On this account also it tends to be omitted in clinical records

(3) It occurs in varying degrees of severity—several mild but definite cases have been noted in which the defect was completely missed by observant parents

(4) Like other inherited conditions, it is becoming more difficult to investigate, because more frequent travel leads to wider dispersal of families, and the general practitioner with his unique facilities for observation is becoming less a "family doctor"

It is believed that the condition is occasionally acquired, but normally is inherited as a dominant character with the unusual feature that a complete generation may be omitted owing to mild deformities being overlooked. Indeed it has been suggested that the defect may reach vanishing-point while the gene remains to become manifest in a subsequent generation.

It is generally assumed that the appearance of any such defect in lineal descent through three or more



g 1—Pedigree showing transmission of funnel chest (black symbols) as a dominant character. Symbols marked with a cross indicate persons in whom the presence or absence of funnel chest is not known.

NUMBERS OF AFFECTED AND UNAFFECTED OFFSPRING OF AFFECTED PARENTS

the stool was positive for E.H. on the third day, but no stool was available afterwards.

The mode of action of the sulphonamides is uncertain. There is accumulating evidence that secondary bacterial infection of the bowel may precipitate an acute attack of amœbic dysentery and be responsible for chronicity in other cases; hence it is possible that the elimination of such infections by the sulphonamides is the reason for the symptomatic improvement. But the rapid disappearance of E.H. from the stools in 5 cases suggests that the drugs may be lethal to the amœbæ. Further research along these lines has been impossible here, and the temptation to treat a series of cases on prolonged courses of chemotherapy without recourse to emetine and to follow up these cases in hospital was not considered justifiable. However, two points emerge clearly: (1) the exhibition of sulphonamides to undiagnosed cases of diarrhœa will lead to some cases of amœbic dysentery being missed; and (2) sulphonamides are a further weapon in the anti-amœbic armoury.

After these cases were observed it became the custom to use a short course of chemotherapy together with emetine as initial treatment in acute amœbiasis, the following course being adopted:

Days 1–10	..	Emetine gr. 1
Days 1– 3	..	Sulphapyridine (or sulphathiazole) total 14–20 g.
Days 4–13	..	Carbasone gr. 4 b.d.
Days 14–20	..	Rest
Days 21–30	..	E.B.I. gr. 1–3 nightly (according to tolerance)

Altogether, 42 cases of acute amœbiasis were treated on these lines. Of those it was possible to follow up 15 at an interval of two to four months after discharge from hospital. The results of treatment and follow up were as follows:

	No. of cases
Cases treated	42
Stools returned to normal within 2 days	30
Stools returned to normal within 3 days	10
Stools returned to normal within 4 days	2
Intolerant to sulphonamides	2
Positive stools on discharge	—
Sigmoidoscopic evidence of disease on discharge	—
Cases reviewed 2–4 months later	15
Positive stools (3 examinations)	—
Sigmoidoscopic evidence of relapse	—
History of diarrhœa of more than 24 hours' duration since treatment	4

It is unwise to draw many conclusions from so few cases. But the results, both immediate and remote, of this treatment have been impressive, and it is hoped that those in a better position to treat large numbers of cases will consider this treatment worthy of further trial. For, if acute amœbiasis is curable, the problem of relapsing amœbiasis ceases to exist.

AMŒBIC HEPATITIS

The subject of amœbic hepatitis has been ably reviewed (*Lancet* 1944) and the importance of acute hepatitis emphasised. Acute amœbic hepatitis presents such a striking clinical picture that the condition may be confidently diagnosed in the absence of confirmation by stool or blood examination. The most striking feature is severe pain of sudden onset in the upper abdomen (either central or to the left or right of the midline). The pain, once established, is unremitting but may be intensified by deep breathing, sudden movement, or taking food. High fever is present, and the victim looks ill and "toxic." Careful examination reveals an enlarged and extremely tender soft liver. The presence or absence of leucocytosis is not important (see below). Response to emetine *is dramatic. The disease is commonly mistaken for a perforated viscus or* cholecystitis. The following case is a typical exam

TABLE II—ANALYSIS OF CASES OF AMŒBIC

Type of case	Case no.	Previous dysentery or severe diarrhœa	Leucocyte-count per c.mm.	Stool examination
Acute amœbic hepatitis	1	No	13,200	Neg.
	2	No	12,600	Active E.H.
	3	No	14,500	Active E.H.
Chronic amœbic hepatitis	4	Yes	4000	E.H. cysts
	5	No	5800	Neg.
	6	Yes	6300	Neg.
	7	Yes	13,400	Active E.H.
	8	Yes	5400	Neg.
Amœbic liver abscess	9	Yes	20,600	Active E.H.
	10*	Yes	7800	Neg.

* This airman died, before treatment was given, from the *of a liver abscess into the pericardium.* The confirmed at autopsy.

A flying-officer, who had been overseas for a year and no history of previous illnesses, had severe epigastric of sudden onset "like constant indigestion" for four before admission. Repeated vomiting did not relieve the On the day of admission the pain became much worse, and was admitted with a diagnosis of acute cholecystitis.

On admission he was febrile (103°F) and ill; he had a brown tongue, and there were scattered rhonchi througho chest. The whole of the right side of the abdomen w and the right upper rectus so firm as to give the impr of a hard abdominal mass. In the right flank and to th of the midline the liver was palpable, soft, and extr tender. The total white-cell count was 13,200 per c.mm., (10,800) being granulocytes. He was seen in conjunction a surgical colleague, and it was decided to start a cour emetine and await events. The response to this was im diate; the pain was less next day and disappeared on third day. He became afebrile on the fifth day, and liver was impalpable on the tenth. No E.H. or cysts found in the stools. He returned to full flying duties weeks after admission.

Chronic amœbic hepatitis is such a well-establi entity that no comments will be made on this subj beyond including cases in table II. These cases included in an attempt to elucidate three points: the leucocyte-count in amœbic hepatitis; (2) the p portion in which stool examination *is positive* for E. and (3) the proportion giving a previous history dysentery.

It is generally accepted that a leucocytosis is distinctive feature of amœbic hepatitis (Manson-B 1943), but only 5 of these cases had a count of ov 10,000, and others showed a moderate leucopeni Only 6 out of the 10 gave a previous history of diarrhœ and in 5 no E.H. or cysts were found in the stools. It my opinion that no reliance can be placed on the histo the white-cell count, or stool examination in the diagno of hepatic amœbiasis. They may give useful confirm tory evidence but are by no means essential to th diagnosis. This must be made on clinical grounds, a confirmation is readily forthcoming from the dramat response to emetine therapy.

SUMMARY

In Ceylon during the period 1944–45 half the ca admitted to a R.A.F. hospital with diarrhœa had amœb dysentery.

The exhibition of sulphonamides in cases of acu amœbic dysentery often causes well-marked clinic improvement and renders stool examination negati *for E.H. As amœbiasis is* by far the commonest ca racted with acetone-water produced little or no depres- of growth suggests the possibility that the poor wth with maize meal may not be due entirely to a ciency of some dietary essential as suggested by the k of Salmon (1947), but that additional factors may involved such as the imbalance of amino-acids in ze (cf. Krehl et al. 1946), or the presence of an actable toxamine (cf. Woolley 1946). Feeding eriments with crude acetone-water extracts and with tions derived therefrom failed to give us conclusive ults.

view of the possible effects of the intestinal flora on synthesis and destruction of nicotinic acid (Ellinger and manuelowa 1946) and of tryptophane, and hence on the irements of nicotinic acid by the animal, we have tried ng succinyl sulphathiazole (1%) to the control diet, ther with supplements of folic acid. Although the rats consistently well on this diet when nicotinic acid was d, without it they showed the same proportion with essed growth as on the simple 10 5% casein diet without bacteriostatic agent. Again indole-3-acetic acid had no tically significant effect on the proportion of rats with essed growth.

CONCLUSIONS

n our earlier note, we pointed out that indole-3- tic acid occurs in maize as a precursor and not as the free substance. Our present findings now make it seem very unlikely that the latter substance can be responsible as such for the apparently more constant "pellagragenic" activity possessed by maize. Apart from this, the principal impression left by our recent results and those of other workers is the erratic response of the rat, used as test-animal for work on nicotinic acid. The suspicion that microsynthesis may be of special importance as a disturbing factor is strengthened, and the variability of our findings with indole-3-acetic acid as an inhibitor of growth for rats is paralleled by those of Perlman and of Dubos and others working with various types of bacteria.

Notes to Table

1. Male piebald rats (Hartwell strain) are transferred from full diet to experimental powder diet when weighing 57–63 g. parate cages, food and water *ad lib*

2. "Average weekly gain in weight" is measured from the th to 35th day on the experimental diet. Growth is counted as "retarded" if the rat grows not more than 5 g in any 10-day period after the 14th day.

3 *Basal diet:* 3% cotton seed oil, 5% salt mixture, 0 15% tine, casein as shown above, and sucrose to 100 In diets containing yellow maize meal (unextracted or extracted), the oil, salts, and cystine content are reduced by 40%. The following vitamins are added to each kg. of diet: choline, 2 g., Ca pantothenate, 20 mg.; aneurine, 3 mg.; pyridoxine, 3 mg.; riboflavine, 3 mg ; biotin (free acid), 0 1 mg.; 'Radiostoleum' (+ 0 1% of 2 methyl,1,4-naphthoquinone), 8 drops; 5% tocopherol acetate, 1 drop on palettes 3 times weekly per rat; folic acid, 0·04 mg., when added, was given on palettes 3 times weekly.

generations is, in the absence of consanguinity, conclusive evidence of its dominant inheritance. The ratio of affected to unaffected members of the family should be 1: 1, or any deviation from this ratio should not be significant. In this family the ratio is 4 : 5, assuming that those members recorded as unaffected are in fact free from even a slight deformity (see table).

On the other hand, funnel chest, as it is usually met with in a population, rather resembles a recessive character, and it may be that the few pedigrees like the present one represent a rare but different mode of transmission.

SUMMARY

Six cases of funnel chest occurred in lineal descent through four generations in a single family in which there was no consanguineous marriage.

Three of the cases (personally observed) strongly suggest that the funnel chest was inherited as a dominant character.

I am indebted to Dr. J. R. Mitchell, school medical officer to Birmingham Education Committee, for permission to publish this case.

From the Dunn Nutritional Laboratory, University of Cambridge and Medical Research Council

SINCE the publication of our preliminary report (1946) on the effect of indole-3-acetic acid on the growth of rats maintained on diets low in protein, nicotinic acid, and tryptophane, we have been continuing our trials, as shown in the accompanying table.

In our earlier experiments the control rats fed on the basal diet (containing 10·5% casein) grew well at an average rate of 15 g. per week, the range being from 8 to 18 g. Addition of nicotinic acid caused no significant increase. Other rats on the same basal diet plus 15 mg. of indole-3-acetic acid per kg. of diet showed a retardation of growth in 19 out of 32 cases, and this could be counteracted by either nicotinic acid or tryptophane.

Since then an irregular proportion of our control rats *on the basal diet,* varying from one experiment to another, have shown a depression of growth (15 rats out of 80) reversible by nicotinic acid or tryptophane, whereas formerly they grew well. There seems to be no correlation between this depression and litter, season, &c. Similar experiences of unexpectedly poor growth on the basal diets, which had previously proved satisfactory, have been reported by Krehl et al. (1947). In our later experiments, moreover, the proportion of rats on the indole-3-acetic acid diet showing a depression of growth (viz., 19 out of 70) is no longer significantly greater than in the control rats. Increasing the dose of indole-3-acetic acid failed to produce a more definite effect. Kreh let al., using two different strains of rats, also report that they obtained no difference in growth with indole-3-acetic acid.

In our recent experiments, rats fed on 40% maize diets do, however, still show, in nearly all cases, a depression of growth, curable by nicotinic acid or as was the case in our early tests. This diet approximately 10·5% protein. In the search for a toxic factor, the maize meal was extracted by a described by Berger and Avery (1944), which is to remove the indole-3-acetic acid precursor, and of an extraction with acetone-water at pH 10. This cedure also removes a protein fraction. The maize when given at the 40% level promoted a growth in our rats significantly better than that with the unextracted maize, in spite of the fact protein content of the diet had been further by the extraction. The growth with the extracted was equal to or better than that obtained with the 10·5% casein diet. Addition of indole-3-acetic (60 mg. per kg.) to the extracted-maize diet did not any retardation of growth.

COMMENTS

As mentioned above, the different behaviour control rats from that found previously is in line experiences of Krehl et al. (1947), who have that diets low in protein, which were formerly suff for adequate growth, now need, with the same of rats, to be supplemented with nicotinic acid. explanation of this apparently unpredictable behavi of the rats must await further study. In some of experiments the control rats still give consistently growth. Those with depressed growths are eve distributed between litters. There seems to be connexion with season. The strain is bred from a population.

One possible explanation which suggests account for the erratic responses observed by and other workers, would be that the prolonged synthetic diets in the laboratory may encourage a in the bacterial flora, by adaptation. It is ger accepted that a variable degree of bacterial the intestine may influence the body's economy nicotinic acid (and presumably in tryptophane, which its metabolism is connected). On this hypoth our failure now to find a significant depression of grow with the addition of indole-3-acetic acid to the might be connected with a change in the intestin flora.

It seems of significance in this connexion that Perlm (1940) has observed that indole-3-acetic acid has in a depressing effect on the organism *Strep. fæcalis* in vit reversible by nicotinic acid or tryptophane. The bacter is capable of adaptation to indole-3-acetic acid by rep transfers, and then ceases to be inhibited by it (Perlm private communication). Indole-3-acetic acid is of cou here to be regarded as an anti-tryptophane substance. Dub (1946) also reports inhibition of the growth of *Mycob tuberculosis, Strep. hæmolyticus, Strep. salivarius,* and *Shig paradysenteriæ* by indole-3-acetic acid, reversible by tryp phane. Handler (1947) on the other hand, found no eff on other organisms, *Strep. fæcalis, Lactobacillus arabinos Staph. aureus, Proteus vulgaris, Aerobacter aerogenes,* *Escherichia coli*, unless high concentrations of the indole acetic acid were employed; and similar findings for *E.* are reported by Raoul (1947). Yet another if somew different kind of example of a variable response to indole acetic acid is mentioned by Cohen and Fowler (1947), found that bacteriophage synthesis was stimulated by sample of indole-3-acetic acid, but they were unable to rep the effect with other samples.

Maize, we still find, produces a significant depress in growth, compared with that in our control rats on a casein diet containing the same total content protein. This agrees with the findings of Krehl et (1947). though here again a variable factor is appare as they now report that rats of the "Yale" str grow better on their niacin-unsupplemented corn-g ration than did the "Sprague-Dawley" strain of that they used earlier. Our finding that maize suggested that the onset of thrombosis may be told by estimations of fibrinogen B and of the thrombin-time, in conjunction with the body perature. Fibrinogen B, described by Lyons in trala. is an intermediate substance produced in the version of fibrinogen into fibrin. Thrombin consists wo components, neither of which will, alone, convert inogen into fibrin. The thrombin component A ts with fibrinogen to form the intermediate product inogen B, which normally passes rapidly into the in form. Mayes suggests that in the prethrombotic e the fibrinogen B fraction is greatly increased and t this increase is pathognomonic of incipient thrombis. Dr. Payling Wright has observed, however, that fibrinogen B always rises after operation: and proombin activity is increased even in the absence of onstrable thrombosis. She concludes that the only able method of detecting thrombosis is careful clinical ervation.

ostoperative blood changes are not only chemical: platelets increase from the fifth or sixth day and h a maximum about the tenth day, thereafter iding to normal by the end of the third week. The nt of the rise is directly correlated with the severity he tissue damage at operation. In 1942 Dr. Payling ght showed that after operation the platelets not y increase in numbers but become more adhesive, stickiness being maximal on or about the tenth day. appears that this effect is attributable to the new ing cells which enter the circulation in response to stimulus of trauma. The closely parallel course of mical and cytological changes suggests a common nulus; and it seems likely that the stimulus to the e-marrow is provided by products of tissue autolysis.

ots originate usually in the small plantar and calf : but the spread of the clot into the venous trunks well be influenced by the physical features in the veins. Formerly anatomists believed that Pout's ligament, by constricting the veins at the level of pelvic brim, played an important part in thrombosis. Payling Wright holds that this ligament is too erior and too lax to exert pressure. By running ster-of-paris into the veins of cadavers and dissecting t the cast she has demonstrated anteroposterior ttening of the vein as it passes into the pelvis: but is flattening is caused by the vein lying almost directly the bone as it passes from the leg to reach the sterior wall of the pelvis. The effect is best likened the kinking of a piece of rubber tubing drawn over e edge of a table. The cross-sectional area of the in at the narrowest point averages 28 sq. mm., compared with 36 and 39 sq. mm. 5 cm. below and above is point. The slowing of the blood and the nipping the clot at the area of narrowing may contribute to e formation of small emboli which break from the attached surface of the thrombus; and this may be he site of origin of repeated non-fatal emboli in femoral rombosis. The making of the venous casts brought o light the fact that whereas in the supine position here is little distortion of the vein except for the flatening, in Fowler's position the vein is bent almost to right-angle; this obstruction must promote the propaation of any thrombus forming in the peripheral veins f the leg.

The circulation-time from leg to carotid sinus slows rogressively up to the eighth or ninth day after operaion, when it becomes steady at the reduced velocity. It is assumed that this slowing depends upon stagnation n the legs since the arm-carotid time is altered less. Dr. Payling Wright is now testing this theory by injecting the radioactive sodium$_{24}$ into the dorsal veins of the foot, the gamma emanations being recorded by a shielded Geiger counter placed over the femoral vein in the groin. One case investigated in this way exemplified the value of foot movement as a pumping mechanism for stagnating blood. Sodium$_{24}$ was injected into the foot of a subject with severe varicose veins. By the end of a minute no radioactive sodium had reached the counter: at that moment the patient contracted his foot dorsally a little, and within 2 sec. a shower of gamma-rays was recorded.

Dr. **Magnus Haines** emphasised that thrombosis may be unaccompanied by symptoms or signs. The time of onset varies: thrombosis may start less than ten days before operation or later than three weeks afterwards; and necropsy shows that it may occur without operation, especially in those who have been some time in bed. The patient is usually over 40 years of age. Clinically, a subsequent pulmonary embolism may be misdiagnosed as pneumonia or basal collapse. Unfortunately clinical records of postoperative thrombosis are usually scanty. At the Chelsea Hospital for Women deaths after abdominal operations have steadily decreased during the past twenty years. Twenty years ago physiotherapy was introduced as part of the postoperative treatment; but the fall in deaths is not due simply to a diminished incidence of thrombosis.

Mr. **A. Dickson Wright** agreed that Fowler's position should be abandoned, except in special circumstances. The patient should sit up except at night and during his afternoon siesta. Among the factors predisposing to thrombosis are the retention of the patient in bed for several days before operation; preliminary starvation and purgation; and loss of blood at operation. A patient with a thrombophilic history should never be submitted to intravenous anæsthesia, pyelography, or cystography; and if operation is undertaken on such a patient it would be worth while to tie his femoral veins at the same time; ligation of these veins does not interfere with everyday activities. Thrombosis manifests itself in many different ways. It may reveal itself through pulmonary embolism; it may be first detected in varicose veins, and this, though it carries no danger of embolism, may be a portent of thrombosis elsewhere: a large loosely attached thrombus may form in one of the deep veins, and cause tenderness, and pain aggravated by dorsiflexion of the foot, and an increase in temperature or pulse-rate. For all these manifestations Mr. Dickson Wright advocates ligation of both femoral veins: once this is done, he argues, the worst is known. Massive femoral thrombosis—phlegmasia alba dolans—causes collapse by abstraction of fluid; and intravenous saline may be needed. Injection of the lumbar ganglia with 1–2% procaine, as recommended by Leriche, ends the arterial and venous spasm; and the cold clammy leg becomes warm. Dos Santos, of Lisbon, using phlebography, has proved the practicability of a planned operation for the abstraction of clots. Mr. Dickson Wright advocates heparin and dicoumarol in all cases of postoperative thrombosis.

Mr. **Leslie Williams** agreed with Mr. Dickson Wright that the initial dose of intravenous heparin should be 125 mg.; thereafter 100 mg. should be given every 4–5 hours except at night when 125 mg. is again injected. Heparin is continued until the delayed effect of dicoumarol appears; 300 mg. of dicoumarol is given on the first day and 200 mg. on the second day. The dose of this drug has to be checked against the prothrombin-time; the aim is to get this time just over twice the normal. Ligation of both femoral veins for thrombosis in one calf is classified by Mr. Williams as "blood-and-iron surgery."

Dr. **K. P. Ball** quoted figures for cases observed at the Central Middlesex Hospital: by the use of anticoagulants the recumbent period for thrombotic patients has been reduced from 45 to 8 days; and their total stay in hospital has been reduced to 3 weeks. Anticoagulants diminish the risk both of embolism and of after-effects.

Mr. **John Howkins** held that Trendelenburg's position may be a focus of trauma. Insufficient heed has been paid to the possibility of a clot originating at the site of operation—especially a second-cut operation or one at a septic site. In the promotion of thrombosis subtotal hysterectomy is a bigger offender than total. What kills the patient is not the clot—this does not occupy the whole lumen—but obstruction by spasm; and perhaps old-fashioned remedies such as papaverine should not be forgotten.

Another speaker was supported in his suggestion that some makes of heparin contain pyogenic substances and may even give rise to anaphylactoid reactions. If heparin causes pain when injected into the skin it will probably cause a reaction when given therapeutically.

Medical Societies

ROYAL SOCIETY OF MEDICINE

ON Oct. 7 Mr. GEORGE PERKINS delivered his presidential address to the section of orthopædics on

Flat-foot, or Instability of the Long Arch

No concept is more muddled in the surgeon's mind, he said, than that of flat-foot. Hordes of children with normal, if low, arches are still referred to outpatient departments from school clinics, with a needless waste of the time of physiotherapists and of overburdened mothers. The term "flat-foot" is misleading, for a high arch is as likely to cause symptoms as a low one; symptoms depend on the stability, not the height, of the arch. The bones of the foot are so shaped that when stress is transmitted through the centre of the subtaloid-midtarsal joint the arch withstands the body-weight without collapsing. It is the duty of the leg muscles to keep this joint in the neutral position, like the staywires of a mast, so that they themselves and the ligaments of the foot take little or none of the strain. But, should the composite joint begin to capsize, as it does if the axis of weight transmission starts to deviate, the stretched ligaments reflexly excite a muscular contraction which restores the status quo. The other essential for stability is the plantigrade position of the foot, with the heel and the heads of the first and fifth metatarsals all on the ground together. Children do not acquire a good reflex balancing mechanism until their second year, and often subside into planovalgus while learning. The reflex mechanism may not be acquired until the age of three or four years, or it may never be developed, so that the feet always collapse on standing.

In clinical examination, stability of the foot can be tested by noting the alignment of leg and foot. If a vertical line through the centre of the knee cuts, or falls outside, the second toe there is no planovalgus. Even if this line falls inside the second toe there may still be no flattening, for some people possess a talus with a neck directed abnormally outwards, so that the foot is externally rotated on the leg. The clue is to look from behind at the angle of the heel, which shows whether the subtaloid-midtarsal joint is capsized or not. The power of active restoration of the arch is shown by noting the new position of the knee-toe axis when standing on tiptoe. Mobility is tested in the ordinary way with the patient lying, and it is always possible to recognise valgus deformity by the prominence of the head of the talus between medial malleolus and navicular, in spite of the masking tendency of any forefoot varus which may be present.

From the point of view of causation and treatment, Mr. Perkins divides flat-foot into four main groups. The common mobile planovalgus due to faulty postural activity of muscle is normal under the age of two years. The routine practice of wedging the inside of the heel in children is fatuous, for no shoe grips a child's foot tightly enough to prevent it turning over into valgus. Boots are necessary, and should be used until the deformity disappears. Wedging the sole is harmful, for it induces a varus of the forefoot, besides making the sole too rigid for a good gait, and there seems to be no point in forward prolongation of the heel. Regarding physiotherapy, the classical inversion exercises overdevelop the *tibialis anterior* and *produce an inversion* of the forefoot which itself tends to cause a valgus of the heel. A much better exercise is to stand with the feet firmly planted on the ground and forcibly rotate the legs outwards at the ankle. In the second group of cases the tripod plantigrade arrangement has been upset in some way. If there is an equinus deformity which lifts the posterior pillar off the ground, this is compensated by a dorsiflexion at the subtaloid-midtarsal joint, but at the expense of some eversion and abduction and general instability. This valgus ex equino has long been known, and in a boy it is a simple matter to perform a subcutaneous elongation of the Achilles tendon. Because such an operation alters the shape of the calf, it seems wiser in a girl to anticipate the fashions of adolescence by simply raising the heel. The other cause of upset of tripod balance, rather neglected until recently, is varus the forefoot: if the first metatarsal head is the ground it can only be brought down by a pensatory valgus of the hindfoot. The cause of a varus is obscure; it may arise from a failure calf muscles or the tibialis anterior to keep pace growth of the bones in development. In tr *is necessary to manipulate the heel into varus forefoot into valgus, if need be with two wrenches, and fix the overcorrected position in* Finally, there is the rigid painful flat-foot of a severe forms of which Mr. Perkins fuses the sub midtarsal joint in the plantigrade position by the triple arthrodesis. Before doing this, it is worth a rigid arch-support, or stiffening the leather at inner border of the shoe, and some form of plastic may eventually be the solution.

DISCUSSION

Mr. SAYLE CREER paid tribute, as had Mr. I to the importance of Lambrinudi's work. He d with Mr. Perkins's view that the bones of the long uphold themselves, for his experiments with amputated limbs have shown that the foot flatt under a weight as soon as all the ligaments have divided. Therefore in some cases a surgical on the ligamentous soft tissues may be justified, is in certain cases of club-foot. He cited also numerous surgical techniques for treating a for varus by bringing down the first metatarsal head, Lambrinudi's procedure for what he called metat primus elevatus.

Sir THOMAS FAIRBANK stressed again the im as a causative factor of inversion of the forefoot hindfoot, and the difficulty of its correction. He raises the inside of the sole (though Sir Robert was in the habit of so doing), and, for capsizing in small children over two, favours a removable covered cork insole worn inside a boot. General and correct walking are more important than any exercises.

Mr. J. S. BATCHELOR thought that true flat-f a rare congenital condition. In the ordinary case is a simple, postural valgus deformity, to be treated children by wedging the heel and stiffening the in border of the sole. Many exercises only aggravate existing equinus deformity.

Mr. V. O. SNELL remarked that the pathology is oft considered upside down. The trouble is really internal rotation of the tibia on the foot, and cure is to walk with the toes turned in, so as re-educate the tibialis posterior, for it is fatigue of t muscle which allows the tibialis anterior to prod varus of the forefoot, and boots may exacerbate t tendency.

Mr. J. A. CHOLMELEY mentioned that shoes are oft too stiff nowadays and need vigorous bending to rest their flexibility.

Mr. PERKINS, winding up, agreed that there is a congenital flat-foot with the talus fixed in equinus a the other bones dorsiflexed. Spasmodic flat-foot is a true instability but a peroneal spasm reflex to arthritis of the subtaloid joint.

Postoperative Thrombosis

A meeting of the section of obstetrics was held Oct. 17, with Mr. A. J. MCNAIR, the president, in th chair.

Dr. HELEN PAYLING WRIGHT said that pulmonar embolism complicates one in about a hundred ma operations; and one out of every six cases of emboli is fatal. Thrombosis, which is almost twice as comm in females as in males, follows most commonly operati in which the abdominal cavity is opened and the pel viscera are explored.

After operation the plasma fibrinogen first diminish and then increases; and by the third or fourth day reaches nearly double the preoperative value. Similarl the prothrombin level, after an initial fall, ris achieve a maximum about the tenth day. Lately Mr.

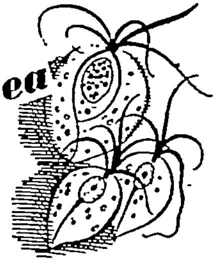
IN GENERAL PRACTICE

Obesity

The advantage of 'Elityran'—full-gland thyroid with high, standardised iodine content—is that it provides complete substitution therapy with minimum risk of by-effects.

'ELITYRAN'

Packings of 30, 100, 250 tablets



Leucorrhoea

Trichomonas vaginalis infection yields to 'Devegan', usually in a few days, and normal flora reappears. Treatment must continue for some time, to prevent recurrence.

'DEVEGAN'

Packings of 30, 150 tablets

Allergic Asthma

Symptomatic relief of allergic asthma may be consistently obtained with 'Franol,' a combination of anti-spasmodic, cardiac stimulant and sedative :— ephedrine, theophylline and 'Luminal.'

'FRANOL'

Packings of 20, 100, 500 tablets

Insomnia

For general purposes the ideal is a medium-strength hypnotic, producing a full night's sleep without subsequent "hangover." 'Phanodorm' is the *classical* medium hypnotic.

'PHANODORM'

Packings of 10, 50, 250 tablets

Reviews of Books

Medicine

Vol. I. *The Patient and His Disease.* A. E. CLARK-KENNEDY, M.D. Camb., F.R.C.P. Edinburgh: E. & S. Livingstone. 1947. Pp. 383. 20*s.*

Dr. Clark-Kennedy's book is "intended to correlate the facts; and, by cutting across the conventional boundaries which separate one branch of medicine from another, emphasise the general principles underlying medicine as a whole." It is "intended to inculcate an attitude of mind . . . to prevent facts which could be deduced from principles being committed to memory unnecessarily . . . to provide a framework on which a knowledge of medicine can be built by self-education as experience widens."

It opens with a clear swift synopsis of what the universe looks like to the modern scientist-philosopher—everything from energy and matter, through life, evolution, and heredity up to consciousness and mind, all in forty pages. This is the patient's background. Then come two long chapters on symptoms and signs. The mental and the physical are both considered. A technique of history-taking and examination is sketched. The common symptoms are described, and their physiological mechanisms explained. Then they are lined up, looked at, classified, and pondered. There are those which are understandable on the basis of students' anatomy and physiology, and those, like tumours, which mean nothing to one who has not studied pathology. There are those expressing defect of structure or function, and those expressing excess, while a few like the extensor plantar response are reversions to primitive mechanisms. There are those which result directly from the impact of injury or disease upon the organism, and those which belong to the organism's living reaction to the impact, tending to its own preservation; yet these latter seem sometimes to be excessive. This is the first step towards seeing disease as one aspect of the interplay of organism and environment.

The next is a chapter entitled Heredity and Environment, which breathlessly describes human development, nutrition, and senescence, the forms of injury and disease according to their causes, drugs and poisons, micro-organisms, new growth, and the relation to health of mind, philosophy, and religion. It is almost purely descriptive, but it provides a basis for the two following chapters in which the phenomena of disease are closely analysed as reactions of the body-cum-mind to environmental change—whether "normal" changes like those of the weather or the personal relationships of everyday life, or "abnormal," like injury and disease—the reactions themselves varying according to the constitution of the body-cum-mind, influenced by its heredity, its age, and its experience.

The second volume, soon to appear, will be largely concerned with diagnosis and treatment. The book thus formed can hardly replace the standard textbooks—there will always be too many tidy-minded teachers to allow that. But the older student and the younger teacher will be attracted by the vigour of its style and its courageous attempt to stand on two feet and face the whole universe. Its author designed it, not as a new medicine, but as "a corrective long overdue in that dangerously over-complicated prescription which is administered to the would-be doctor in the present day"; and it should achieve much of the purpose for which it was written.

In this bold venture Dr. Clark-Kennedy's chief handicap is his attempt to be too comprehensive. He wishes to comprehend among his readers both the student, beginning medicine, and the established practitioner or teacher. He writes sometimes for one, sometimes for the other. He feels he must comprehend in his text all the main facts which form the content of the many branches of medicine he covers. Skilfully though he does it—and he has a genius for terse statement and provocative simplification—the facts pile up in places indigestibly, and obscure the generalisations. Nor are they always quite accurate, though that in the author's eye would be a minor matter; an occasional slip just emphasises his impatience to survey the whole territory of medicine and show that it does have a pattern of its own independent of the existing fields and this, in the main, he succeeds, though his pattern is doubtless not final. His plea that the should be described, should be accepted in general teachers and practitioners, and should constitute background of their teaching and their practice, powerful one.

Principles and Practice of War Surgery

(3rd ed.) J. TRUETA, M.D. Barcelona, HON. D.SC. surgeon E.M.S., Wingfield-Morris Orthopædic Oxford. London: Hamish Hamilton and W. 1946. Pp. 426. 42*s.*

THE value of Dr. Trueta's work lies in his synth known facts into a system for the treatment of wounds; and the appearance of the third edition book, at first sight ill timed since most of the have gone home, is useful in recording his views on injuries which present much the same in peace as in war. His five-point programme of surgery, wound cleansing, wound excision, and immobilisation is the theme running through book from its early chapters on the pathology of and infection to its later detailed consideration technique. It is not a complete treatise on surgery, because it does not deal with wounds of abdomen, chest, or head. It would teach a young only how to deal with cases which, in civil life, would considered orthopædic problems. But everyone embarks on traumatic surgery should read the and the illustrations are superb.

Ernährungsprobleme in Mangelzeiten

Die schweizerische Kriegsernährung 1939–46. FLEISCH, Ordinarius für Physiologie, Direktor Physiologischen Institutes an der Universität Lau Präsident der Eidgenössischen Kommission für ernährung. Basle: Schwabe. 1947. Pp. 518. Sw.

BEFORE the war the Swiss imported a large part of food. About half their calories came from abroad the major imports were wheat and sugar. It was inevitable therefore that, like the belligerent they should have difficulties over their food-sup during the war; and as the conflict went on round borders the screw of rationing gradually had to tightened up. Tea and coffee, the first to be ratio were followed in July, 1941, by fats and then eggs, milk, and meat. In the end the extraction bread was raised to 90% and nearly everything potatoes was rationed. Coupons had to be given up restaurant meals. There was no serious black ma and the general effects of rationing were not un those in this country. Bread was rationed however, and the country passed through a bad perio in the late spring of 1945 when the calories for the norm consumer fell to about 1800 per day, and the intake fat to 40 grammes per day and of protein to 54 g. p day. Like all countries forced to ration calories, th Swiss had special supplements for workers in variou categories, and they had, naturally, special allocation of certain foods for children. Invalids also, particularly diabetics, had special rations. The 90% extractio bread was found to suit sick persons very well.

This and much more is set out in the book, whose histori value will be considerable, particularly to the Swiss though it must always have interest for anyone versed in the theory and practice of rationing: nothing so complete about rationing and its effects seems to have been published elsewhere. The changes in weight and hæmoglobin in the general population, which seemed to be related to fluctuations in the rations, would be important if they could be confirmed and their causatio established.

New Ways of Treating Uræmia (London: J. & A. Churchill. 1947. Pp. 112. 10*s.* 6*d.*).—This is an Engli reprint of Dr. W. J. Kolff's original publication, "The Artificial Kidney,"[1] with some additional case-histories, and brief addenda on his experiences with peritoneal lavage, perfusion of isolated loops of gut, and high-caloric/low-protein diets in the treatment of uræmia. The book is chiefly concerned with artificial kidney technique.

The Integration of Medicine

HE pile of human knowledge has grown prodigi- ly—mostly, it seems, in the last few thousand rs. In that time man's mind and brain have nged little, so that an individual's capacity to sp and use knowledge is now minute in com- ison with the knowledge at his disposal. That is reason why man's use of knowledge lags so far ind his accumulation of it. Since the knowledge uired for one task, such as making a motor-car, beyond one man's comprehension, it must be uired piecemeal by many men, and these must n develop a method of working together for its rdinated application. That group effort encounters otional difficulties as its greatest stumbling-block. t even the intellectual problem of the subdivision abour is not easy. The group needs its specialists, in the minute details of their narrow fields, its "generalists" who, seeing the pattern of the e task, can modify it to suit changing needs or ging techniques. The "generalist" must know ough of the specialist's field to influence and to influenced by him; the specialist must know ough outside his field to make him interested in s fellows and able to work with them. The mass- roduction motor manufacturers have developed a attern of functional relationships among their mployees that seems to dovetail very well. under e pressure of their overriding aim to make and sell rs at a profit. Their task was relatively easy; r the aim was simple, and the degree of success in ach part of the organisation, as well as in the whole tructure, was measurable in money. In most other arge-scale human activities the problem is the same —namely, to organise the work of large numbers of ndividuals, equipped with diverse knowledge and kill, into a coöperative effort; but where the aim is not capable of precise definition, and the progress towards it not amenable to arithmetical measurement, the difficulty is enhanced; and where it is further desired that every person taking part should feel his loyalty engaged, and his powers fully used, the problem becomes a major one.

Medicine in Britain is at grips with that problem today It has been discussed widely, and profitably, from political, social, economic, and administrative points of view. The first experimental structure is taking shape. So far, however, little has been written on the changes that will be necessary in the intellectual equipment and outlook of doctors, if they are to fulfil their rôles adequately and happily in that structure Is the knowledge we give them in the schools, and are the skimmings thereof that we sample in examinations, the most suitable for their purpose? We expect general practitioners to supervise the health of men, women, and children in all walks of life, and to advise them in matters of employment, recreation, and social and family relationships, as well as in things of the body only. We expect clinical specialists to undertake, alone or with the practitioner, the care of the whole patient for a time, not merely to replumb his stomach or give an opinion on his heart. We look to a service where the study and the well-being of a patient will oftener than in the past be the task of several doctors working together. Is the present training of the specialist calculated to make him fit in well in a team, or does it tend to make him superior in his own field and indifferent to all else—content for example to pronounce the patient's heart normal and not interested in the cause of her pain? Do our general practitioners have such a grasp of medicine as a whole that they can see the full possibilities of good for every patient, and can call in the specialist as an expert colleague rather than as a member of a superior order?

Questions of this kind have exercised the mind of Dr. CLARK-KENNEDY, who as a teaching fellow of a Cambridge college and dean of a London medical school has for many years played an active part in medical education. He has concluded that medicine is in serious danger from the dominance of specialism. Increasingly narrow specialists are not the best people to control the teaching of the undergraduate student. Their organisation is primarily determined by techniques, and by the numbers and needs of patients in hospitals or in practice. These subdivisions are inappropriate for teaching purposes, especially of the future general practitioner, who must always deal with man in the round. Yet teaching in the clinical period has unthinkingly followed the hospital organisation into specialties, with all too little coordination or coöperation between them. The textbooks have followed suit, and even the general physician no longer writes about general medicine. but at most edits a composite collection of specialists' monographs. So strongly does Dr. CLARK-KENNEDY deplore this threatened disintegration of medicine —which, incidentally, could be hastened by a mechanically organised national health service—that to try to counteract it he has set pen to paper in an effort to put all medicine between the covers of two volumes, the first of which is described in our review column this week. When complete his book should be the most unorthodox treatise on medicine that our generation has seen.

Not the least important feature of the author's pattern of medicine as a whole is his frank recognition that a doctor, dealing (as he must) with a patient's mind as well as with his body, introduces into the relationship his own philosophy of life—his own views on the relation of mind to body, on the scope of free will and moral responsibility, and on the nature and function of religion These things cannot be left at home, in any honest attempt at doing the doctor's task thoroughly. So the doctor would be wise to make up his mind about them, at least to the extent of a working hypothesis. Dr. CLARK-KENNEDY's own hypothesis is that mind exists in parallel with matter, that man's behaviour is influenced not solely by his genes and his environment but in some degree by his own free will, and that "it may still be best to retain the age-long conception of the real existence of the human soul."

A MEDICAL COMMONWEALTH

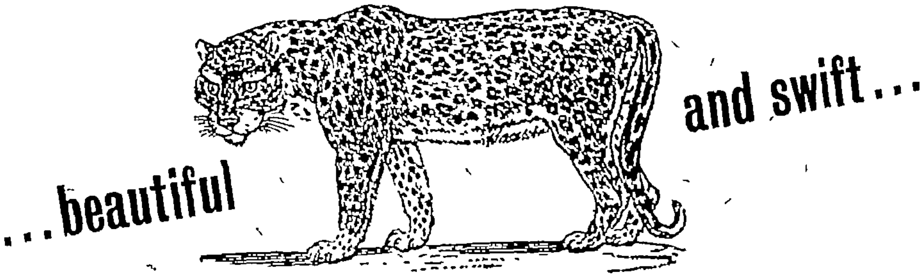
Kaplin is as familiar to the obstetrician in India as Kaplon is to his counterpart in Britain both names represent the same Glaxo vitamin K analogue preparations Such vowel changes are sometimes necessary in some countries . . in Havana, for example, Fersolin names the efficient iron treatment that London knows as Fersolate

Discuss vitamin D injections for allergic disorders with medical men in Egypt or Australia and you will hear of Calci-Ostelin Discuss chilblain treatments with British practitioners and someone is sure to mention Colloidal Calcium with Ostelin Both are one and the same preparation by merely a different name

Not all the names of Glaxo products change on leaving England. Prepalin is still Prepalin in Prague; amethocaine hydrochloride is Anethaine as much in Colombo as in Capetown, Mersagel is known wherever dhobie itch is prevalent, whether in Syria Singapore or the Sudan, and Penicillin Glaxo is demanded as such the world over

Almost every product of Glaxo is available almost everywhere . . reflecting an export-mindedness that dates back to the beginnings of the Company, and forward to the re-establishment of Britain's leadership in every corner of the world.

GLAXO LABORATORIES LTD
GREENFORD, MIDDLESEX, ENGLAND
Other factories and laboratories in England at Barnard Castle, Driffield, Stratford and Ulverston (under construction)
In Argentina, Australia, India, Italy and New Zealand Agents in almost every country in the world.



ON THE LITHENESS of the leopard depends his safety; survival depends on adaptation to environment. Man, too, must adapt himself to modern conditions. Failure in 'adaptation' leads to certain functional deficiencies, the rational treatment for which may be the use of the natural sex hormones (steroids).

The B.D.H. range of sex hormones includes forms for all accepted methods of administration. Oestroform is preferred for all states of ovarian hypofunction. Detailed information is available on request.

may abort whitlows it will do so only if given fore the stage at which they are usually presented the doctor; most patients suffer in silence until s has formed, and no kind of chemotherapy can pplant the evacuation of pus. All the same. nicillin is a notable adjunct to surgery of the fingers: d when bone and tendon sheaths—both tissues th a poor resistance to bacterial invasion—have en invaded it may make the difference between normal and a crippled hand. It remains to be cided whether, as D'ABREU et al. suggest, penicillin ould be given intramuscularly for all types of hand d finger infection, or whether it is ineffective in lp infections except when the deeper tissues are volved. It should be easy to collect enough cases settle this point one way or the other, and the ladies which afflict the finger of our workpeople erve a first priority in medical research.

Complications in Feeding Experiments

THE days are passing when it was possible to say at the presence of a particular vitamin in the diet a man or animal prevents the corresponding ficiency disease, and conversely that the absence the vitamin necessarily leads to the development that disease. We now recognise various complicag factors, some of which prevent the organism from eloping the deficiency disease when the vitamin is ent, while others immobilise or inactivate the amin and so induce a conditioned deficiency or vert a potential into an actual deficiency. For ample, it is now clear that the prevention or duction of rickets in man or animal depends not ly on the amount of vitamin D in the diet but also the intake and balance of certain mineral elements, e presence of anticalcifying factors, the acidogenic operties of the diet, and so on. Again, the requirements of vitamin B_1 depend on the calorie intake; t fat is vitamin-B_1-sparing, and enough fat can event a deficiency in rats when the diet is devoid the vitamin. Another complicating factor is the currence of different forms of a given vitamin. itamin D_2 is roughly equivalent to D_3 for the rat human but not for the chick. The vitamin-A tivity of a food is not the same as its vitamin-A content; there are various provitamins A (carotenoids) which differ in potency, and the degree of absorption and utilisation of a particular provitamin A may vary from one food to another. Furthermore, the vitamins needed by man are not all needed by certain other animals—thus vitamin C is needed by man, but rats, farm animals, and nearly all other mammals do not need any in their diet because they can synthesise it in vivo.

In the case of several of the B vitamins, two complicating factors which have been coming into prominence are the possible influence of microsynthesis in the alimentary canal of the host and the influence of so-called anti-vitamins or "toxamins." A third factor, a still more troublesome factor to the investigator, is the variable response of the animal used for experiment: but this may be a reflection of variations in the alimentary microflora. These variable factors are well illustrated by recent observations on nicotinic-acid deficiency. Until a year or so ago only human subjects, dogs, and monkeys seemed suitable for studies on this vitamin. Rats, it was found, thrived when there was no nicotinic acid in their diet, presumably having synthesised it or obtained it from alimentary microfloral activity. It then appeared that the rat could be used for nicotinic-acid experiments, provided the diet was deficient in protein and particularly in tryptophane (an amino-acid which seems to be involved in nicotinic-acid deficiency). and that maize, which perhaps contained some anti-vitamin factor, was included in the diet.[1] Now, however, a further unexpected complication has arisen in these experiments, for several observers have reported a puzzling variability and lack of consistency in the behaviour of their animals. KREHL et al.[2] find that their control rats, which formerly grew satisfactorily on a non-maize, low-protein diet without nicotinic acid, no longer do so. A similar experience is recorded by Dr. KODICEK and colleagues in this issue. Moreover these Cambridge workers, who formerly found that indole-3-acetic acid, a substance structurally related to tryptophane, depressed growth in a proportion of their rats, no longer find a statistically significant difference from the controls. The most plausible explanation seems to be that some variable bacteriological factor is involved. This gains support from the independent observations of PERLMAN,[3] who found that indole-3-acetic acid, no doubt because of its ability to "block" tryptophane, antagonised the growth of *Streptococcus fæcalis*. This organism could however adapt itself to the indole-3-acetic acid. It seems likely that the erratic results obtained in animal experiments have a similar explanation. That is to say, micro-organisms under some circumstances can either destroy or synthesise nicotinic acid or other nutrients; whereas under changed conditions they may fail to do so. In keeping with this general picture are the results of DUBOS,[4] who finds that indole-3-acetic acid inhibits the growth of various other micro-organisms, and that the inhibition is reversed by tryptophane; whereas other workers,[5] using yet other micro-organisms, find that indole-3-acetic acid has no effect unless given in very high concentration.

It still remains uncertain whether the apparent pellagragenic activity of maize is due essentially to a toxamin—an anti-nicotinic-acid or an anti-tryptophane substance—or whether some other combination of factors is responsible, such as its low content of tryptophane and perhaps some other amino-acids. Other workers have reproduced the growth-depressing effects on rats without using maize at all,[6] as by the addition to the diet of gelatin, acid-hydrolysed casein, or an appropriate mixture of isolated amino-acids.[7] Probably each of these factors, then, can influence the "pellagragenic" properties of a diet—the deficiency of nicotinic acid, a deficiency or imbalance of certain amino-acids, the presence of a toxamin, and the type of bacterial activity in the gut. The action of bacteria is undoubtedly the most difficult to predict or control. Present uncertainties

Septic Finger

THE chief of a surgical firm who insisted on treating infections of the fingers himself would provoke some astonishment. Yet ill-advised or faulty treatment of a severe infection of a finger may easily impair a man's working capacity for life. The hand is the tool on which most of mankind depend for their bread, but it still receives less than its due attention from experienced surgeons—hence the small amount of information published on the effects of penicillin on hand infections.

The great bulk of whitlows or felons (both of which are strictly speaking lesions of the fingers) and infections of the hand are caused by penicillin-sensitive staphylococci. So it was not surprising when FLOREY and WILLIAMS[1] found that local applications of penicillin would relieve pain, expedite recovery, and prevent complications in all types of whitlow. The papers we publish this week bear out their broad conclusions with one exception—both WEBSTER and BOLTON and colleagues found that penicillin makes little difference to the healing of simple pulp infections. Their controls and their penicillin-treated series healed in about the same time, even though the intramuscular administration they used is acknowledged to be more effective than the local applications which shortage of supplies forced on FLOREY and WILLIAMS. The pulp of the fingers, if properly treated, has a high natural resistance to infection. Once tension has been relieved by suitable incisions its vascularity ensures an abundance of fresh leucocytes and tissue fluids and only meddling will prevent healing in a reasonable time. But while WEBSTER found penicillin ineffective in all pulp infections, BOLTON and colleagues make a clinical distinction between uncomplicated pulp infections, whose cure is not hastened by penicillin, and "suspected bony *felons," in which penicillin is invaluable.* Into the latter class they put those pulp infections in which, though there is no X-ray evidence of bone infection, suppuration has continued for a long time, there is much necrosis of the soft tissues, or inadequate incisions have already been made without relieving symptoms. Without penicillin such cases progress to frank osteomyelitis of the phalanx, but with it the X-ray signs of osteomyelitis never appear or else appear and promptly regress. In their report of 7 cases of pulp infection treated at the Westminster Hospital with intramuscular penicillin, D'ABREU and colleagues[2] do not make such distinctions, but they report a reduction in average disability from 21 days in controls to 9 9 days; they gave the penicillin either in water or in beeswax-oil, in a dose of 150,000–300,000 units morning and evening for 2–4 days.

Finger infections are so important that it is worth while restating the principles of their treatment. All forms of hand surgery should be done under adequate anæsthesia. The ethyl-chloride spray, with its painful induction, its uncertain and fugitive analgesia, and its capacity for petrifying the tissues is worse than useless The surgeon must have sufficient time and tissues of normal texture on which to work. He must be able to see exactly what he is doing; and the requisite bloodless field is easily secured by applying a sphygm tourniquet. The incision for simple pulp should be a lateral one, not crossing the the finger-tip to lay the pulp open like a for a finger thus "kippered" will lose much precision as a tactile instrument. The incision however be deep enough to cut all the fibrous which divide the pulp up into compartments, may well be made from both sides The is as important as the operation, and the dressers carry it out should wear masks. Dressings not be frequent, should never be moist, and ensure rest for the finger in its normal po rest. Tulle gras, covered by dry gauze, backed plaster slab, and changed every fourth day these requirements. If there is doubt whet infection is spreading or has spread beyond the intramuscular penicillin is needed, and 100,000 twice a day is probably the minimum effective for routine outpatient use. It is doubtful heat is useful—it is certainly harmful if it is mo The hypertonic dressings seem to be falling out favour: sodium sulphate solution macerates the and magnesium sulphate paste is painful W infection has spread to the bone of the termi phalanx, healing is certain to take a long time, tho penicillin may well halve it. Penicillin must how be given for much longer than is usual with tissue infections, which is not surprising in the of experience with subacute osteomyelitis elsewh The surgical measures required when osteomye has supervened are much the same as with si pulp infections except that loose pieces of bon any size should be picked out. Excision of the d part of an infected phalanx before natural separat has occurred is a disastrous operation which leave deformed finger-tip and prevents that regeneration the phalangeal diaphysis (*after radiological eviden* of its complete disappearance) which was often se before penicillin and is now still more common

The most dramatic application of penicillin to t surgery of the fingers is in tendon-sheath infection Before the introduction of penicillin, infection of t tendon sheath usually meant that the patient wou be left with a stiff claw which he would gladly s amputated. CRUICKSHANK and HARRISON found th 13 unselected tendon-sheath infections in pre-penicill days led to 9 fingers being amputated and 2 left stiff now, with penicillin, they report only 1 amputatio and 1 stiff finger in 13 similar cases. D'ABREU et al mention one illuminating case of a nurse with a seve incipient tenosynovitis which was aborted in twenty-four hours by giving a single dose of 500,000 units Penicillin, it seems, has reversed the prognosis of thecal whitlows besides greatly hastening recovery Inpatient treatment, general anæsthesia, and a bloodless *field, however, are more important than ever* The sheath is opened in the palm through an incision which need only be large enough to relieve tension CRUICKSHANK and HARRISON advocate early movement; once the sheath has been decompressed movement is painless, and it must help to prevent the adhesions between the tendon and its sheath which are the main cause of stiffness.

In the hand, as elsewhere in the body, penicillin is not a substitute for properly planned surgery. Though may abort whitlows it will do so only if given ore the stage at which they are usually presented the doctor; most patients suffer in silence until has formed, and no kind of chemotherapy can plant the evacuation of pus. All the same, icillin is a notable adjunct to surgery of the fingers; when bone and tendon sheaths—both tissues h a poor resistance to bacterial invasion—have n invaded it may make the difference between ormal and a crippled hand. It remains to be ided whether, as D'ABREU et al. suggest, penicillin uld be given intramuscularly for all types of hand finger infection, or whether it is ineffective in p infections except when the deeper tissues are olved. It should be easy to collect enough cases settle this point one way or the other, and the ladies which afflict the finger of our workpeople erve a first priority in medical research.

Complications in Feeding Experiments

THE days are passing when it was possible to say it the presence of a particular vitamin in the diet a man or animal prevents the corresponding iciency disease, and conversely that the absence the vitamin necessarily leads to the development that disease. We now recognise various complicag factors, some of which prevent the organism from reloping the deficiency disease when the vitamin is ent, while others immobilise or inactivate the amin and so induce a conditioned deficiency or ivert a potential into an actual deficiency. For ample, it is now clear that the prevention or duction of rickets in man or animal depends not ly on the amount of vitamin D in the diet but also the intake and balance of certain mineral elements, presence of anticalcifying factors, the acidogenic operties of the diet, and so on. Again, the requirents of vitamin B_1 depend on the calorie intake; t fat is vitamin-B_1-sparing, and enough fat can event a deficiency in rats when the diet is devoid the vitamin. Another complicating factor is the currence of different forms of a given vitamin. tamin D_2 is roughly equivalent to D_3 for the rat human but not for the chick. The vitamin-A tivity of a food is not the same as its vitamin-A ntent; there are various provitamins A (carotenoïds) hich differ in potency, and the degree of absorption d utilisation of a particular provitamin A may ry from one food to another. Furthermore, the tamins needed by man are not all needed by certain her animals—thus vitamin C is needed by man, t rats, farm animals, and nearly all other mammals not need any in their diet because they can nthesise it in vivo.

In the case of several of the B vitamins, two mplicating factors which have been coming into rominence are the possible influence of micronthesis in the alimentary canal of the host and the ifluence of so-called anti-vitamins or "toxamins." third factor, a still more troublesome factor to the ivestigator, is the variable response of the animal ed for experiment, but this may be a reflection f variations in the alimentary microflora. These ariable factors are well illustrated by recent observaions on nicotinic-acid deficiency. Until a year or o ago only human subjects, dogs, and monkeys seemed suitable for studies on this vitamin. Rats, it was found, thrived when there was no nicotinic acid in their diet, presumably having synthesised it or obtained it from alimentary microfloral activity. It then appeared that the rat could be used for nicotinic-acid experiments, provided the diet was deficient in protein and particularly in tryptophane (an amino-acid which seems to be involved in nicotinic-acid deficiency), and that maize, which perhaps contained some anti-vitamin factor, was included in the diet.[1] Now, however, a further unexpected complication has arisen in these experiments, for several observers have reported a puzzling variability and lack of consistency in the behaviour of their animals KREHL et al.[2] find that their control rats, which formerly grew satisfactorily on a non-maize, low-protein diet without nicotinic acid, no longer do so. A similar experience is recorded by Dr. KODICEK and colleagues in this issue. Moreover these Cambridge workers, who formerly found that indole-3-acetic acid, a substance structurally related to tryptophane, depressed growth in a proportion of their rats, no longer find a statistically significant difference from the controls. The most plausible explanation seems to be that some variable bacteriological factor is involved This gains support from the independent observations of PERLMAN,[3] who found that indole-3-acetic acid, no doubt because of its ability to "block" tryptophane, antagonised the growth of *Streptococcus fæcalis.* This organism could however adapt itself to the indole-3-acetic acid. It seems likely that the erratic results obtained in animal experiments have a similar explanation. That is to say, micro-organisms under some circumstances can either destroy or synthesise nicotinic acid or other nutrients, whereas under changed conditions they may fail to do so. In keeping with this general picture are the results of DUBOS,[4] who finds that indole-3-acetic acid inhibits the growth of various other micro-organisms, and that the inhibition is reversed by tryptophane; whereas other workers,[5] using yet other micro-organisms, find that indole-3-acetic acid has no effect unless given in very high concentration.

It still remains uncertain whether the apparent pellagragenic activity of maize is due essentially to a toxamin—an anti-nicotinic-acid or an anti-tryptophane substance—or whether some other combination of factors is responsible, such as its low content of tryptophane and perhaps some other amino-acids. Other workers have reproduced the growth-depressing effects on rats without using maize at all,[6] as by the addition to the diet of gelatin, acid-hydrolysed casein, or an appropriate mixture of isolated amino-acids.[7] Probably each of these factors, then, can influence the "pellagragenic" properties of a diet—the deficiency of nicotinic acid, a deficiency or imbalance of certain amino-acids, the presence of a toxamin, and the type of bacterial activity in the gut. The action of bacteria is undoubtedly the most difficult to predict or control. Present uncertainties

Septic Finger

THE chief of a surgical firm who insisted on treating infections of the fingers himself would provoke some astonishment. Yet ill-advised or faulty treatment of a severe infection of a finger may easily impair a man's working capacity for life. The hand is the tool on which most of mankind depend for their bread, but it still receives less than its due attention from experienced surgeons—hence the small amount of information published on the effects of penicillin on hand infections.

The great bulk of whitlows or felons (both of which are strictly speaking lesions of the fingers) and infections of the hand are caused by penicillin-sensitive staphylococci. So it was not surprising when FLOREY and WILLIAMS[1] found that local applications of penicillin would relieve pain, expedite recovery, and prevent complications in all types of whitlow. The papers we publish this week bear out their broad conclusions with one exception—both WEBSTER and BOLTON and colleagues found that penicillin makes little difference to the healing of simple pulp infections. Their controls and their penicillin-treated series healed in about the same time, even though the intramuscular administration they used is acknowledged to be more effective than the local applications which shortage of supplies forced on FLOREY and WILLIAMS. The pulp of the fingers, if properly treated, has a high natural resistance to infection. Once tension has been relieved by suitable incisions its vascularity ensures an abundance of fresh leucocytes and tissue fluids and only meddling will prevent healing in a reasonable time. But while WEBSTER found penicillin ineffective in all pulp infections, BOLTON and colleagues make a clinical distinction between uncomplicated pulp infections, whose cure is not hastened by penicillin, and "suspected bony felons," in which penicillin is invaluable. Into the latter class they put those pulp infections in which, though there is no X-ray evidence of bone infection, suppuration has continued for a long time, there is much necrosis of the soft tissues, or inadequate incisions have already been made without relieving symptoms. Without penicillin such cases progress to frank osteomyelitis of the phalanx, but with it the X-ray signs of osteomyelitis never appear or else appear and promptly regress. In their report of 7 cases of pulp infection treated at the Westminster Hospital with intramuscular penicillin, D'ABREU and colleagues[2] do not make such distinctions, but they report a reduction in average disability from 21 days in controls to 9·9 days; they gave the penicillin either in water or in beeswax-oil, in a dose of 150,000–300,000 units morning and evening for 2–4 days.

Finger infections are so important that it is worth while restating the principles of their treatment. All forms of hand surgery should be done under adequate anæsthesia. The ethyl-chloride spray, with its painful induction, its uncertain and fugitive analgesia, and its capacity for petrifying the tissues is worse than useless The surgeon must have sufficient time and tissues of normal texture on which to work. He must be able to see exactly what he is doing; and the requisite bloodless field is easily secured by applying a sphyg
tourniquet. The incision for simple pulp
should be a lateral one, not crossing the
the finger-tip to lay the pulp open like a
for a finger thus "kippered" will lose much
precision as a tactile instrument. The incision
however be deep enough to cut all the fibrous
which divide the pulp up into compartments,
may well be made from both sides. The
is as important as the operation, and the
carry it out should wear masks. Dressings
not be frequent, should never be moist, and
ensure rest for the finger in its normal
rest. Tulle gras, covered by dry gauze, backed
plaster slab, and changed every fourth day
these requirements. If there is doubt wh
infection is spreading or has spread beyond the
intramuscular penicillin is needed, and 100,000
twice a day is probably the minimum effective
for routine outpatient use. It is doubtful w
heat is useful—it is certainly harmful if it is mo
The hypertonic dressings seem to be falling out
favour: sodium sulphate solution macerates the
and magnesium sulphate paste is painful. Wh
infection has spread to the bone of the te
phalanx, healing is certain to take a long time, th
penicillin may well halve it. Penicillin must how
be given for much longer than is usual with
tissue infections, which is not surprising in the
of experience with subacute osteomyelitis elsew
The surgical measures required when osteomy
has supervened are much the same as with si
pulp infections except that loose pieces of bon
any size should be picked out. Excision of the di

acts on the adrenal only, and that all the other ts are secondary results of adrenal failure. He tains that hypoadrenia alone will account for defects e eye, heart, ear, teeth, brain, and stomach. He ittle puzzled as to how the lens and the inner ear egulated during the second month by the adrenal. nakes a gallant effort to square the circle by remarking hat "since the lens is derived from the forebrain mall size might easily result" from insufficient al control; in fact the lens is derived from surface erm. But Brown's hypothesis is based on a more mental error. The adrenal itself is a late develop-. The anlage of the cortex, it is true, is present g the second month, but there is no trace of the lls until the end of the sixth week. No secretion renaline is possible till the end of the organogenetic d (end of third month) and no lipoid or chromaffin on can be obtained before the sixth month. It very unlikely, therefore, that the regulation of ogenesis (which is disturbed by rubella) is related r endocrine activity comparable to that of post-life. The genes, the organisers, and the growth nts themselves are mapping out the endocrine ls during the first three months, and the problem t of experimental embryology, not adult pathology. poplastic adrenals are found in post-rubella infants in Swan's cases they were not) are they not likely an additional manifestation of the suppressive n of the virus on rapidly differentiating structures, r than the primary lesion?

important new pathological concept of extrinsic al interference with organogenesis, introduced by standing Australian work, will only be thoroughly d when embryologists, pathologists, obstetricians, atisticians tackle it together. There is no need onalise, since the subject is easily accessible to ment and observation.

LEISURE FOR PRACTITIONERS

ORTLY after the annual representative meeting of British Medical Association a correspondent in the sh *Medical Journal* took the representatives to task se they had rejected a proposal from Paddington t in any National Health Service adequate provision be made for a rota of practitioners for duty at t, weekends, holidays, and during sickness." He rded this rejection as contrary to the trend of present on among practitioners. Actually, however, the sal was rejected because the representative body that arrangements of this kind are better made ly and spontaneously rather than by central decree. is a matter in which in fact local action is beginning ar fruit.

mingham produced one of the earliest schemes, h was designed to give insurance practitioners dom at weekends. From 3.30 P.M. on Saturday to A.M. on Monday the medical work needing to be e (at the Saturday evening surgery or by urgent ing) is concentrated in the hands of the duty practitioners, while the others are free to be at leisure. city area has been divided into sections suited to purpose, and all practitioners willing to accept r turn of responsibility are free to join in the ngements. Notices are posted in the surgeries giving ents the dates on which their own doctor will be out each, and the name of the doctor who will be acting him. A similar scheme at Bolton aims at giving ore freedom on the afternoons of Wednesday, day, and Sunday. According to press reports, on h of these afternoons and evenings there will be a rota four doctors (from among fifty practising in Bolton) ilable for emergency work. This seems at first sight rather small proportion to remain accessible, and it l be interesting to learn whether it proves sufficient.

Press cuttings from other parts of the country give fewer details, but are evidence of a growing desire on the part of practitioners to have their own arrangements established before the arrival of the appointed day. Much good can come of these experiments and we hope that more may soon be heard—perhaps at the coming Panel Conference—about their results in practice.

STERNUM AND HEART

DEPRESSION of the lower end of the sternum is fairly common, for Lang[1] noted it in 3·5% of children during their first year at school. On another page Sainsbury records a family in which 6 mild cases occurred in four generations—apparently as a dominant character. The effect of this defect on the position of the heart is apparently not always appreciated, seeing that Evans[2] recorded 16 examples in adults who were referred for a second opinion because of suspected heart disease. In 5 of these patients rheumatic heart disease had originally been diagnosed, while another 4 had been relegated to grade 3 or 4 by medical recruiting boards. Yet another, a lad of 19, had on the advice of his doctors discontinued work as a medical student and had subsequently been placed in grade 4 by three different medical boards after examinations which included a radiologist's report that the heart was greatly enlarged. When seen by Evans all 16 were found to be healthy, "handicapped only by the restriction imposed on them by a medical examination that had misinterpreted the clinical and radiological signs."

All these patients had depression of the lower sternum, which Evans divides into three types. The first type is the deepest, or "funnel," depression, of which there were 2 examples in Evans's series; the anteroposterior diameters of these patients' chests were $4^1/_2$ and 5 in. In the second type, the "cup" depression is somewhat shallower: Evans had 8 examples of this kind, with anteroposterior diameters between $5^1/_4$ and $5^3/_4$ in. In the shallowest, or "saucer," depression, of which there were 6 examples, the anteroposterior diameter ranged from 6 to $6^1/_4$ in. In every patient with sternal depression the apex-beat was displaced to the left—sometimes beyond the anterior axillary line—and there was a mid-systolic murmur best heard at the left edge of the depression. It was presumably the combination of this murmur with the displacement of the apex-beat that had usually led to the erroneous diagnosis of heart disease. The radiological findings were outstanding. In the 2 patients with a funnel depression the heart was displaced bodily to the left, but there was no change in the shape or size of the cardiac outline. In the patients with a cup depression the anterior film showed slight or moderate enlargement of the cardiac outline with prominence of the pulmonary arc, but the oblique view showed that the cardiac silhouette was normal. With the saucer depression the findings were similar to those with the cup depression, but less pronounced. Other features were the transparency of the cardiac shadow in the anterior view on screening, and in the left oblique films the displacement backwards of the heart until it overlapped the vertebræ and the constriction of the so-called aortic window.

Evans's explanation is based on his finding that in 16 healthy adults the anteroposterior diameter of the chest averaged $7^3/_4$ in. and was never less than 7 in., while the anteroposterior thickness of the heart was 3 in. and the thickness of the sternum, vertebral column, and the soft tissues covering them about $3^3/_4$ in. If the anteroposterior diameter of the chest is less than the sum of these last two figures—i.e., $6^3/_4$ in.—the heart is compressed and thereby has its lateral limits extended. If this compression is gross, as in the funnel depression, may perhaps find their counterpart in the earlier history of vitamin B_1, when it was found that an irregular proportion of rats maintained on a diet devoid of the vitamin unaccountably failed to develop symptoms of deficiency. The trouble was later identified and given a name, "refection"—a phenomenon due, as we now know, to a peculiar type of fermentation of the food brought about by changed bacterial action in the intestine.

Annotations

BUILDING THE HEALTH SERVICE

IN an address last week to the Institute of Public Administration Mr. John L. Edwards, parliamentary secretary to the Ministry of Health, referred to the undisputed deficiencies of the present medical organisation. National Health Insurance benefits only twenty-one million people, and some of the uninsured are deterred from seeking medical advice by the cost; under the existing system continuity of treatment is not assured; doctors are badly distributed; the general practitioner works too much in isolation; the hospital system has grown up haphazard, the service varying from good to very bad; and the mental health services are cut off from other branches. Discussion in Parliament was centred not on the existence of these problems but on how best to deal with them; and the Act which emerged did no more than give the powers necessary for the establishment of a new service.

This service is divided into three main branches: hospital, general-practitioner, and local and domiciliary health services. At the Ministry progress has been greatest with the hospital services. In formulating the fourteen hospital regions the first aim was to provide a good planning unit. The areas are designed for administrative purposes, and there is no intention to confine patients within the boundaries of their own region. The regions vary in size—Manchester has four million people, while Oxford has under one million—and the performance of the different regions as planning units will be compared. Members of regional boards were not chosen as delegates or representatives of interested bodies. Selection was difficult, but "judging by the criticism we have received we have done it fairly well." The work of the boards is going to make heavy demands on the members' time. The Minister's wish is that in setting up hospital management committees the boards shall be guided not so much by size as by function. *Management committees may be appointed* to a single hospital or to a group of hospitals: there is no rigid formula. The Minister will advise on the types of organisation to be consulted before the committees are appointed; but otherwise the regional boards will have a free hand. A list of hospitals and of convalescent homes coming under the Act has been prepared by the Ministry; but the future of some hospitals will not be settled at once, and in a few cases the question may be referred for arbitration. Public-assistance institutions now house both sick and fit, and protracted negotiation will be required before all the sick are in hospitals under the regional boards and only the healthy are accommodated in these institutions. Local authorities have been asked to readjust their staffs so that the boards will get sufficient personnel and the authorities will not be unduly deprived; the allocation is important for the officers concerned, since those who come under the boards will benefit by the new superannuation scheme, which, Mr. Edwards suggests, is the most flexible yet devised.

Hitherto the creation of the machinery for the general-practitioner service has proved a straightforward task. Nearly all of the local executive councils have now been formed, and these are working in harmony beside the old insurance committees. Local authorities enjoined to use voluntary services, and, for th running of part 3 services, to devolve to subcommittees in various parts of county areas.

In moulding the service decentralisation has be reconciled with central supervision; the must, for example, supervise finance. A common throughout the country is not wanted, but the should also not be much worse in one area others. It will be particularly difficult to d much the Minister should interfere with hospital p *and development; considerable delegation is* plated, but expert advice from the centre may be In general, the guiding principle is that decisions be made at the lowest possible levels. Even so, objective criteria for judging performance, of hospitals, must be evolved. In the service h cratic methods are to be shunned; there sho neither delay in treatment nor too much form- the Ministry is investigating the possibility of and simplifying forms, but "I am not too o for checks are necessary to avoid abuse of the

Under the Act doctors may engage in both and private practice. The danger here is that *may provide a better service for private patients;* this were to happen and patients were not to use service, the whole scheme would fail. Thus the must be to set a high standard; but though for maintenance of this standard disciplinary machinery necessary there will still be complete clinical free The ideal should be to treat patients in their ordi social environment. Much of the work now done clinics could be restored to practitioners if these relieved of routine and were provided with be facilities; and here group practice and health cen are important. The practitioner must be restored the position he used to occupy.

Between the three arms of the new service there bound to be frontier difficulties and boundary disput This has been acknowledged by allowing for over in the constitution of bodies and for the passing on proposals from one body to others. Much will dep on the readiness of bodies to see the service as a whole and for complete success much will still rest with th public.

HOW DOES RUBELLA ACT ON THE EMBRYO?

THE response to the original observations of Gre and Swan, and Tostevin on congenital defects followi rubella in the mother has passed through the phase scepticism, via surprise, to complete confirmation an acceptance. We may now be entering *the stage* attempted rationalisation of a group of facts for whi no-one except the experimental embryologists seems have been prepared. These embryologists, indeed, in the clinical observations only a satisfying example man of a well-known experimental finding—that th time of application of a noxa to a developing embry determines the resultant developmental defect; th nature of the noxa is much less material, provided th it will retard mitosis. Evidence that diseases other tha rubella can produce similar defects is accumulating, is also a mass of data concerning the variety of defect met with and their relationship to the time of th maternal infection. *This line of work is likely to* yiel fruitful results.

Meanwhile the exact mode of action of the viru remains obscure. If we accept the analogy with the experimental findings—mainly in amphibia—the virus or toxins attack whatever organs are actively developing at the time. This does not explain why, though the defects are widespread, *they do not* extend to all parts of the body. Brown[1] suggests that th

STERNUM AND HEART

DEPRESSION of the lower end of the sternum is fairly common, for Lang[1] noted it in 3·5% of children during their first year at school. On another page Sainsbury records a family in which 6 mild cases occurred in four generations—apparently as a dominant character. The effect of this defect on the position of the heart is apparently not always appreciated. seeing that Evans[2] recorded 16 examples in adults who were referred for a second opinion because of suspected heart disease. In 5 of these patients rheumatic heart disease had originally been diagnosed, while another 4 had been relegated to grade 3 or 4 by medical recruiting boards. Yet another. a lad of 19, had on the advice of his doctors discontinued work as a medical student and had subsequently been placed in grade 4 by three different medical boards after examinations which included a radiologist's report that the heart was greatly enlarged. When seen by Evans all 16 were found to be healthy, "handicapped only by the restriction imposed on them by a medical examination that had misinterpreted the clinical and radiological signs."

All these patients had depression of the lower sternum, which Evans divides into three types. The first type is the deepest, or "funnel," depression, of which there were 2 examples in Evans's series; the anteroposterior diameters of these patients' chests were 4½ and 5 in. In the second type, the "cup" depression is somewhat shallower: Evans had 8 examples of this kind, with anteroposterior diameters between 5¼ and 5¾ in. In the shallowest, or "saucer," depression, of which there were 6 examples, the anteroposterior diameter ranged from 6 to 6¼ in. In every patient with sternal depression the apex-beat was displaced to the left—sometimes beyond the anterior axillary line—and there was a mid-systolic murmur best heard at the left edge of the depression. It was presumably the combination of this murmur with the displacement of the apex-beat that had usually led to the erroneous diagnosis of heart disease. The radiological findings were outstanding. In the 2 patients with a funnel depression the heart was displaced bodily to the left, but there was no change in the shape or size of the cardiac outline. In the patients with a cup depression the anterior film showed slight or moderate enlargement of the cardiac outline with prominence of the pulmonary arc, but the oblique view showed that the cardiac silhouette was normal. With the saucer depression the findings were similar to those with the cup depression, but less pronounced. Other features were the transparency of the cardiac shadow in the anterior view on screening, and in the left oblique films the displacement backwards of the heart until it overlapped the vertebræ and the constriction of the so-called aortic window.

Evans's explanation is based on his finding that in 16 healthy adults the anteroposterior diameter of the chest averaged 7¾ in. and was never less than 7 in., while the anteroposterior thickness of the heart was 3 in. and the thickness of the sternum, vertebral column, and the soft tissues covering them about 3¾ in. If the anteroposterior diameter of the chest is less than the sum of these last two figures—i.e., 6¾ in.—the heart is compressed and thereby has its lateral limits extended. If this compression is gross, as in the funnel depression,

may perhaps find their counterpart in the earlier history of vitamin B_1, when it was found that an irregular proportion of rats maintained on a diet devoid of the vitamin unaccountably failed to develop symptoms of deficiency. The trouble was later identified and given a name, "refection"—a phenomenon due, as we now know, to a peculiar type of fermentation of the food brought about by changed bacterial action in the intestine.

BUILDING THE HEALTH SERVICE

In an address last week to the Institute of Public Administration Mr. John L. Edwards, parliamentary secretary to the Ministry of Health, referred to the undisputed deficiencies of the present medical organisation. National Health Insurance benefits only twenty-one million people, and some of the uninsured are deterred from seeking medical advice by the cost; under the existing system continuity of treatment is not assured; doctors are badly distributed; the general practitioner works too much in isolation; the hospital system has grown up haphazard, the service varying from good to very bad; and the mental health services are cut off from other branches. Discussion in Parliament was centred not on the existence of these problems but on how best to deal with them; and the Act which emerged did no more than give the powers necessary for the establishment of a new service.

This service is divided into three main branches: hospital, general-practitioner, and local and domiciliary health services. At the Ministry progress has been greatest with the hospital services. In formulating the fourteen hospital regions the first aim was to provide a good planning unit. The areas are designed for administrative purposes, and there is no intention to confine patients within the boundaries of their own region. The regions vary in size—Manchester has four million people, while Oxford has under one million—and the performance of the different regions as planning units will be compared. Members of regional boards were not chosen as delegates or representatives of interested bodies. Selection was difficult, but "judging by the criticism we have received we have done it fairly well." The work of the boards is going to make heavy demands on the members' time. The Minister's wish is that in setting up hospital management committees the boards shall be guided not so much by size as by function. Management committees may be appointed to a single hospital or to a group of hospitals: there is no rigid formula. The Minister will advise on the types of organisation to be consulted before the committees are appointed; but otherwise the regional boards will have a free hand. A list of hospitals and of convalescent homes coming under the Act has been prepared by the Ministry; but the future of some hospitals will not be settled at once, and in a few cases the question may be referred for arbitration. Public-assistance institutions now house both sick and fit, and protracted negotiation will be required before all the sick are in hospitals under the regional boards and only the healthy are accommodated in these institutions. Local authorities have been asked to readjust their staffs so that the boards will get sufficient personnel and the authorities will not be unduly deprived; the allocation is important for the officers concerned, since those who come under the boards will benefit by the new superannuation scheme, which, Mr. Edwards suggests, is the most flexible yet devised.

Hitherto the creation of the machinery for the general-practitioner service has proved a straightforward task. Nearly all of the local executive councils have now been formed, and these are working in harmony beside the old insurance committees. Local authoritie enjoined to use voluntary services, and, for th running of part 3 services, to devolve to subcommittees in various parts of county area.

In moulding the service decentralisation has be reconciled with central supervision; the must, for example, supervise finance. A common throughout the country is not wanted, but the should also not be much worse in one area th others. It will be particularly difficult to decide much the Minister should interfere with hospital p and development; considerable delegation is plated, but expert advice from the centre may be In general, the guiding principle is that decisions be made at the lowest possible levels. Even so, objective criteria for judging performance, partic of hospitals, must be evolved. In the service b cratic methods are to be shunned; there sho neither delay in treatment nor too much form the Ministry is investigating the possibility of and simplifying forms, but "*I am not too op* for checks are necessary to avoid abuse of the

Under the Act doctors may engage in both and private practice. The danger here is that may provide a better service for private patients; this were to happen and patients were not to use service, the whole scheme would fail. Thus the must be to set a high standard; but though for maintenance of this standard disciplinary machinery necessary there will still be complete clinical free The ideal should be to treat patients in their ordi social environment. Much of the work now done clinics could be restored to practitioners if these relieved of routine and were provided with b facilities; and here group practice and health ce are important. The practitioner must be restored the position he used to occupy.

Between the three arms of the new service there bound to be frontier difficulties and boundary disput This has been acknowledged by allowing for over in the constitution of bodies and for the passing on proposals from one body to others. Much will dep on the readiness of bodies to see the service as a whol and for complete success much will still rest with t public.

HOW DOES RUBELLA ACT ON THE EMBRYO?

The response to the original observations of Gre and Swan, and Tostevin on congenital defects follow rubella in the mother has passed through the phase scepticism, via surprise, to complete confirmation a acceptance. We may now be entering the stage attempted rationalisation of a group of facts for whi no-one except the experimental embryologists seems have been prepared. These embryologists, indeed, in the clinical observations only a satisfying example man of a well-known experimental finding—that th time of application of a noxa to a developing embry determines the resultant developmental defect; th nature of the noxa is much less material, provided th it will retard mitosis. Evidence that diseases other th rubella can produce similar defects is accumulating, is also a mass of data concerning the variety of defect met with and their relationship to the time of th maternal infection. This line of work is likely to yiel fruitful results.

Meanwhile the exact mode of action of the viru remains obscure. If we accept the analogy wit the experimental findings—mainly in amphibia—th virus or toxins attack whatever organs are actively developing at the time. This does not explain why, though the defects are widespread, they do not exten to all parts of the body. Brown[1] suggests that th acts on the adrenal only, and that all the other ts are secondary results of adrenal failure. He tains that hypoadrenia alone will account for defects e eye, heart, ear, teeth, brain, and stomach. He ittle puzzled as to how the lens and the inner ear gulated during the second month by the adrenal. makes a gallant effort to square the circle by remark- nat "since the lens is derived from the forebrain nall size might easily result" from insufficient al control; in fact the lens is derived from surface erm. But Brown's hypothesis is based on a more mental error. The adrenal itself is a late develop- . The anlage of the cortex, it is true, is present r the second month, but there is no trace of the lla until the end of the sixth week. No secretion enaline is possible till the end of the organogenetic (end of third month) and no lipoid or chromaffin pa can be obtained before the sixth month. It very unlikely, therefore, that the regulation of ogenesis (which is disturbed by rubella) is related endocrine activity comparable to that of post- life. The genes, the organisers, and the growth nts themselves are mapping out the endocrine k during the first three months, and the problem of experimental embryology, not adult pathology. poplastic adrenals are found in post-rubella infants in Swan's cases they were not) are they not likely an additional manifestation of the suppressive of the virus on rapidly differentiating structures, than the primary lesion ?

important new pathological concept of extrinsic al interference with organogenesis, introduced by -tanding Australian work, will only be thoroughly d when embryologists, pathologists, obstetricians, atisticians tackle it together. There is no need ionalise, since the subject is easily accessible to iment and observation.

LEISURE FOR PRACTITIONERS

RTLY after the annual representative meeting of ritish Medical Association a correspondent in the *Medical Journal* took the representatives to task se they had rejected a proposal from Paddington t in any National Health Service adequate provision be made for a rota of practitioners for duty at weekends, holidays, and during sickness." He ded this rejection as contrary to the trend of present on among practitioners. Actually, however, the sal was rejected because the representative body that arrangements of this kind are better made y and spontaneously rather than by central decree. s a matter in which in fact local action is beginning ar fruit.

mingham produced one of the earliest schemes, h was designed to give insurance practitioners om at weekends. From 3.30 P.M. on Saturday to M. on Monday the medical work needing to be (at the Saturday evening surgery or by urgent ng) is concentrated in the hands of the duty prac- ners, while the others are free to be at leisure. city area has been divided into sections suited to purpose, and all practitioners willing to accept turn of responsibility are free to join in the ements. Notices are posted in the surgeries giving nts the dates on which their own doctor will be out ach, and the name of the doctor who will be acting him. A similar scheme at Bolton aims at giving ors freedom on the afternoons of Wednesday, rday, and Sunday. According to press reports, on of these afternoons and evenings there will be a rota ur doctors (from among fifty practising in Bolton) able for emergency work. This seems at first sight ther small proportion to remain accessible, and it be interesting to learn whether it proves sufficient.

Press cuttings from other parts of the country give fewer details, but are evidence of a growing desire on the part of practitioners to have their own arrangements established before the arrival of the appointed day. Much good can come of these experiments and we hope that more may soon be heard—perhaps at the coming Panel Conference—about their results in practice.

STERNUM AND HEART

DEPRESSION of the lower end of the sternum is fairly common, for Lang[1] noted it in 3·5% of children during their first year at school. On another page Sainsbury records a family in which 6 mild cases occurred in four generations—apparently as a dominant character. The effect of this defect on the position of the heart is apparently not always appreciated, seeing that Evans[2] recorded 16 examples in adults who were referred for a second opinion because of suspected heart disease. In 5 of these patients rheumatic heart disease had originally been diagnosed, while another 4 had been relegated to grade 3 or 4 by medical recruiting boards. Yet another, a lad of 19, had on the advice of his doctors discontinued work as a medical student and had subsequently been placed in grade 4 by three different medical boards after examinations which included a radiologist's report that the heart was greatly enlarged. When seen by Evans all 16 were found to be healthy, "handicapped only by the restriction imposed on them by a medical examination that had misinterpreted the clinical and radiological signs."

All these patients had depression of the lower sternum, which Evans divides into three types. The first type is the deepest, or "funnel," depression, of which there were 2 examples in Evans's series; the anteroposterior diameters of these patients' chests were $4^{1}/_{2}$ and 5 in. In the second type, the "cup" depression is somewhat shallower: Evans had 8 examples of this kind, with anteroposterior diameters between $5^{1}/_{4}$ and $5^{3}/_{4}$ in. In the shallowest, or "saucer," depression, of which there were 6 examples, the anteroposterior diameter ranged from 6 to $6^{1}/_{4}$ in. In every patient with sternal depression the apex-beat was displaced to the left—sometimes beyond the anterior axillary line—and there was a mid-systolic murmur best heard at the left edge of the depression. It was presumably the combination of this murmur with the displacement of the apex-beat that had usually led to the erroneous diagnosis of heart disease. The radiological findings were outstanding. In the 2 patients with a funnel depression the heart was displaced bodily to the left, but there was no change in the shape or size of the cardiac outline. In the patients with a cup depression the anterior film showed slight or moderate enlargement of the cardiac outline with prominence of the pulmonary arc, but the oblique view showed that the cardiac silhouette was normal. With the saucer depression the findings were similar to those with the cup depression, but less pronounced. Other features were the transparency of the cardiac shadow in the anterior view on screening, and in the left oblique films the displacement backwards of the heart until it overlapped the vertebræ and the constriction of the so-called aortic window.

Evans's explanation is based on his finding that in 16 healthy adults the anteroposterior diameter of the chest averaged $7^{3}/_{4}$ in. and was never less than 7 in., while the anteroposterior thickness of the heart was 3 in. and the thickness of the sternum, vertebral column, and the soft tissues covering them about $3^{3}/_{4}$ in. If the anteroposterior diameter of the chest is less than the sum of these last two figures—i.e., $6^{3}/_{4}$ in.—the heart is compressed and thereby has its lateral limits extended. If this compression is gross, as in the funnel depression,

The first type is the deepest, or "funnel," depression, of which there were 2 examples in Evans's series; the anteroposterior diameters of these patients' chests were $4^{1}/_{2}$ and 5 in. In the second type, the "cup" depression is somewhat shallower; Evans had 8 examples of this kind, with anteroposterior diameters between $5^{1}/_{4}$ and $5^{3}/_{4}$ in. In the shallowest, or "saucer," depression, of which there were 6 examples, the anteroposterior diameter ranged from 6 to $6^{1}/_{4}$ in. In every patient with sternal depression the apex-beat was displaced to the left—sometimes beyond the anterior axillary line—and there was a mid-systolic murmur best heard at the left edge of the depression. It was presumably the combination of this murmur with the displacement of the apex-beat that had usually led to the erroneous diagnosis of heart disease. The radiological findings were outstanding. In the 2 patients with a funnel depression the heart was displaced bodily to the left, but there was no change in the shape or size of the cardiac outline. In the patients with a cup depression the anterior film showed slight or moderate enlargement of the cardiac outline with prominence of the pulmonary arc, but the oblique view showed that the cardiac silhouette was normal. With the saucer depression the findings were similar to those with the cup depression, but less pronounced. Other features were the transparency of the cardiac shadow in the anterior view on screening, and in the left oblique films the displacement backwards of the heart until it overlapped the vertebræ and the constriction of the so-called aortic window.

Evans's explanation is based on his finding that in 16 healthy adults the anteroposterior diameter of the chest averaged $7^{3}/_{4}$ in. and was never less than 7 in., while the anteroposterior thickness of the heart was 3 in. and the thickness of the sternum, vertebral column, and the soft tissues covering them about $3^{3}/_{4}$ in. If the anteroposterior diameter of the chest is less than the sum of these last two figures—i.e., $6^{3}/_{4}$ in.—the heart is compressed and thereby has its lateral limits extended. If this compression is gross, as in the funnel depression, the whole heart is pushed over to the left, but in the less severe cases the heart is compressed in the "sterno-spinal vice," giving a superficial radiological impression of enlargement. These results illustrate once again how necessary is radiology in the routine examination of the cardiovascular system.

DIABETIC NEUROPATHY

INVOLVEMENT of the nervous system is one of the commoner complications of diabetes mellitus. In the days before insulin Kraus[1] reported abnormal tendon-jerks in 40% of his diabetic patients and impairment of vibration-sense in the legs in a third of them, while in 426 patients studied by Broch and Klovstad[2] some of the jerks were absent in 48·7%. The exact types of neurological involvement, the pathology, and the relationship between the metabolic disturbance and the neurological abnormalities are still doubtful. Jordan[3] divided the neurological complications into four groups—(1) hyperglycæmic, in which tenderness of nerve and muscle, usually without objective signs, is found in patients with a high blood-sugar and responds well to treatment of the diabetes; (2) circulatory, in which there are signs of arteriosclerosis in addition to neurological involvement; (3) degenerative, in which impaired tendon-jerks and poor pupillary reaction to light occur without severe symptoms; and (4) neuritic, where there are relatively serious symptoms and abnormal signs in the legs coming on fairly acutely and gradually improving in the course of weeks or months. Broch and Klovstad found that their cases fell into somewhat similar groups though they have avoided the ætiological terms which Jordan used.

The main symptom of diabetic neuropathy is pain in the legs, which may be very severe, especially at night, and is accompanied by considerable tenderness of the muscles. In the more advanced cases there is wasting and weakness of muscles and sometimes foot-drop, absent ankle-jerks and knee-jerks, and impaired vibration-sense; position-sense in the feet may be lost, resulting in ataxia. Sometimes there is cutaneous sensory impairment, which may be dissociated in type, resembling that found in syringomyelia, and may be in the distribution of spinal root segments rather than in the peripheral-nerve areas commonly affected in other types of peripheral neuritis. Of 100 cases of diabetes with neurological signs Rudy and Epstein[4] noted evidence of spinal-cord involvement in 26, but they did not give details of these cases; in 1904 Williamson[5] demonstrated histological signs of degeneration in the posterior columns of a diabetic aged 25 who died in coma and was known to have had absent knee and ankle jerks. Disturbance of bladder function similar to that found in tabes dorsalis may be associated with the peripheral neuropathy (in 10 of 125 cases reported by Rundles[6]), and in rare cases this may occur without other clinical evidence of neuropathy.

It seems certain that the neuropathy is not the direct result of hyperglycæmia or ketosis; it may be seen in patients whose diabetes is well controlled by diet and insulin,[2] whereas other patients who were free of neurological signs before treatment have developed symptoms and signs shortly after treatment has been started. Inevitably lack of vitamin B_1 has been suggested as the cause, but Needles[7] and also Fein et al.,[8] who from this point of view investigated the diets given to their patients, found that neuropathy when the intake of B_1 was well above requirements. Treatment with large doses of does not notably affect the rate of recovery of patients, and if the vitamin is in any way with the neuropathy it must be in relation to subtle upset of carbohydrate metabolism. Some think there is an important relationship betw pheral vascular disease and neuropathy, and B Klovstad suggest that the neurological invol in some unexplained way the consequence of disturbance; but only about 10% of their had impalpable pedal pulses, incipient g ulceration, while a further 12·5% had other ev vascular disease, such as cerebral arteriosclerosis, pectoris, or retinal vascular changes. Of R 125 cases only 25 had clinical evidence of p vascular disease.

At present, therefore, the pathogeny of neuropathy remains obscure, which makes treatment difficult, other than effective control diabetes. It is usual for slow improvement to place over a period of weeks or months, but patients pains in the calves and ataxia persist knee and ankle jerks are permanently impaired.

ANKYLOSING SPONDYLITIS

THE need for more detailed classification of anky spondylitis was emphasised by several speakers at week's meeting of the Heberden Society. Dr. C Buckley expressed his belief that there may b types: the first type, which attacks adolescents, males, is acute and spreads rapidly; while the which starts in or after the late twenties, is fou predominantly in men and is less acute, with s involvement of the sacro-iliac region in the early Dr. Buckley maintains that the diagnosis shou be made on the strength of sacro-iliac changes these are accompanied by an increased blood-sedi tion rate or characteristic spinal changes. Progr suggested, has been retarded and the truth ma the acceptance of this disease as a form of rheum arthritis. Ankylosing spondylitis is an osteopathy; is evidenced in the spread of connective tissue from bone-marrow and in the osteoporosis, which is extreme. The distinction is borne out in the diff response to gold: gold, which has an affinity for syn tissue, is more or less effective in rheumatoid art whereas in ankylosing spondylitis it does litt no good.

Mr. N. L. Capener could offer little that was ne encouraging in surgical treatment. During the phase he tries to achieve physiological rest by Bradford frame or one of its modifications, com with head retraction. There is little place for the p jacket, and a plaster bed must be used only with *jackets restricting respiratory function* are to be abj The orthopædist's aim is correction of the defor maintenance of the correction, and re-education. O tomy may be needed; osteotomy of the hip is helpful, but cases must be well chosen since by operation patients are on their feet at the expen sitting down. Osteotomy of the spine may give better results; Smith-Petersen has evolved a techn by which multiple excisions are made at the site of old posterior apophyseal joints. With rec procedures the difficulty—apart from biological siderations such as muscle wasting—is that int fascial flaps are almost bound to become ossified. results would be better if the costovertebral joints be mobilised.

Dr. I. G. Williams was uncertain why benefits this condition. Applying, as he does, 300 units to each of two fields daily, irradiation of the

takes three weeks; even where the sacro-iliac alone is affected, he treats every part of the spine. therapy is not without its dangers: the skin is cularly liable to react because of the immediately cent bone: and, since operation may be necessary, ment should not be continued beyond the stage he hard, dry, scaly skin reaction. Moreover, the bility of blood changes has to be borne in mind: in women the sacro-iliac region cannot be effectively ed without exposure of the ovaries to irradiation the risk of artificial menopause and chromosome rmalities. The symptoms of artificial menopause be averted by the administration of œstrogens: there is no evading the danger of chromosome ges, the reality of which has been proved in animals. Williams is thus led to advise against this treatment ny young women wanting children. The benefits adiation are that pain and paravertebral muscular h are reduced, mobility is increased, and the patient ted for orthopædic treatment. In the early stages atient may regain full movement: and even where ondition is advanced pain is relieved. If symptoms after a full course one further course may be given a six-months interval; but the two courses should pervised by the same therapist.

PLANS IN EIRE

re has now produced a white-paper outlining changes contemplated under the Health Act lately ed. Over the next ten years the State is to assume cial responsibility for a steadily increasing proportion health expenditure. At present some £5¼ million re spent each year from public funds, about one- of which is paid direct by the State and five-sixths he local authorities: but it is intended that in years' time just over £9 million shall be allocated, ich half will come from central funds.

r administrative purposes Eire is to be divided three regions, based on the university teaching res of Dublin, Cork, and Galway, and upon these res will be centred institutional services and special ices such as those for cancer, for rheumatism, and pathological investigations. The more direct services, the other hand, are to be administered at a county l by special local health councils on which will be sented the county and county-borough councils, ther with coöpted members "having special knowe of, or interest in, health administration." These th councils will be concerned with tuberculosis, tious diseases, venereal diseases, mother-and-child general-practitioner services "in so far as these ces do not relate to the provision of institutional t and specialist facilities." Each county will be ded into districts served by health units normally sisting of a doctor, a nurse, and a midwife. Properly ipped local health clinics will in time be provided ome with X rays but all with accommodation for dical examinations, for pharmacy, for record-keeping, d for hygiene instruction. In country districts these ics will be adapted where possible from the existing ispensary buildings." A few major health centres will available at selected places to deal with complicated specialised cases sent on from the local clinics.

Unlike those proposed in Great Britain these health vices will not be freely accessible to all who care to e them. Only people whose income is below £250 a ar—or in the case of farmers whose holding is rated a valuation of less than £25—may avail themselves all services unquestionably, and even these may be ked to make token payments to the district medical icer for general-practitioner services (except in respect maternity and child welfare and the treatment of ectious disease). The next income-group (£250–£500, farmers rated at £25–£50) is excluded entirely from participating in the general-practitioner services, but may receive regional services on payment at prescribed rates.

District and county hospitals will provide general hospital services, but only the regional hospitals will offer a full range of specialist investigation and treatment. This is probably inevitable in a country in which so many of the people live in small scattered communities, but good integration and association (including transport) between central and local units will be necessary if hospitals lacking suitable equipment and staff are to be dissuaded from undertaking specialised work. This danger may easily be accentuated by the ambitious plans of hospital building in country areas which to some extent have been already realised with the aid of funds derived by the Hospital Trust from sweepstakes. The trust has at present £9 million which is to be used, together with supplements from local authorities, on a country-wide hospital building programme likely to cost some £30 million. This is the estimate for provision for the acutely sick, and another £13 million will be required before the aged and infirm are properly accommodated.

Judging from this white-paper Eire has much leeway to make up, but is planning resolutely to give her people as good a service as possible within her financial limits.

WHO IS TO PAY FOR MEDICAL FILMS?

THE making of medical films, in the view of the Scientific Film Association's medical committee,[1] should no longer be left to a few enthusiasts, attached to photographic units in universities and medical schools, to public-spirited industrial bodies, or to Government departments (which occasionally produce a few); nor should it be left to commercial enterprise; the cost should be met from public funds. In July Sir Ernest Graham-Little asked the Chancellor of the Exchequer to earmark sums for the production of medical films, and received the reply[2] that it is for the medical schools to apply to the University Grants Committee for funds for this purpose. Besides making grants to universities as a whole, that committee administers an additional Treasury grant of a million pounds a year intended for recurrent grants to medical schools; and the Scientific Film Association propose that a small proportion of this should be set aside for the production and distribution of medical films, possibly by financing a new body to make films for the whole country. A sum of £58,000, they think, would cover an initial two-year programme to supply films for all our medical schools; and this represents only 2½% of the special grant to medical schools over two years. The S.F.A. medical committee could ensure unity of purpose between the film committees in universities and medical schools, those of the British Medical Association and British Medical Students' Association, and the Government departments interested in postgraduate medical teaching; if funds were forthcoming an immediate start could be made with the two-year programme.

THE KING'S SPEECH

IN opening Parliament on Tuesday H.M. the King began by speaking of our "grave economic difficulties, affecting almost the entire world," and of his confidence that in these times of hardship the nation will once again demonstrate its resolution and energy. The Government's first aim will be to redress the adverse balance of payments, particularly by expanding exports, and they will give all possible help to the home production of food. Legislation projected against this sombre background includes Bills for abolishing the poor-law, for reforming the administration of criminal justice, and for extending the scope of public care of children deprived of normal home life.

From the Department of Education of the Deaf, Manchester University

PROBABLY in no other branch of education are the possibilities of progress so great as in the education of the deaf. Unquestionably the most difficult part is the education of children who were born deaf or have become deaf so early in life that they cannot learn to talk in the ordinary way. The official policy of the Ministry of Education and of the Scottish Education Department is to give every deaf child an opportunity of acquiring speech. This is also the policy formulated by the Office of Education of the Federal Government of the United States.

A new conception of this aspect of the education of the deaf has resulted from experimental work with very young deaf children. In the past there was a tendency to emphasise the intellectual needs of deaf children (Story 1915). The teaching of lip-reading and speech was understood and practised in terms of formal schooling (Haycock 1933). Often they were (and sometimes still are) taught piecemeal, in prescribed lessons, very much on the same basis as other school subjects.

It is now possible to develop speech comprehension through lip-reading in deaf children under $2^{1}/_{2}$ years of age, with the result that they make spontaneous attempts to talk. It is advisable to begin training at the age of 6 months or as soon as deafness is discovered. Inevitably this has entailed a different approach from that formerly made with deaf-and-dumb children, who were admitted to school at the age of 5 years or later. With infants and very young children formal methods of teaching are impracticable and unsuitable.

Learning to walk and talk depends on (1) maturation, a factor of inner growth which cannot be brought under environmental control, and (2) the opportunities for learning. With the young child successful learning is always essentially spontaneous; it only takes place in so far as it satisfies the needs of his personality as a whole.

Habits of speech comprehension, vocalisation, and talking are an aspect of a child's growth in personal-social relationships. This growth is as much emotional as intellectual. A baby learns to talk so that his physical, social, and practical needs may be satisfied through the response of others to his attempts to express them vocally. The needs are his, and stages in the development of his body and mind set the pace. In the first place it is his dependence, as an immature and relatively helpless being, on persons stronger and more skilful than himself for life, health, and happiness during the first five years that normally makes those years the natural and optimal period for him to acquire speech.

HOME TRAINING UNDER SUPERVISION

As part of an experiment, 32 deaf children, ranging in age from 12 weeks to nearly 3 years and referred to the research unit at Manchester University for tests, have been given home training by their parents under the guidance of one of us. In every instance but one the children have first developed a habit of watching for speech and have then begun spontaneously to lip-read. These beginnings have been characterised by naturalness and apparent absence of any need to look at the face of the speaker in any fixed or concentrated way. The children seem also to have capacity to grasp the associations that constitute the a new word or phrase with a freedom that sharply with the effort to lip-read that is so in older beginners.

All of the children have vocalised freely whe have wanted something, and many of them vocalised in response to speech. In 16 cases th been spontaneous attempts to say words in ap situations. Such attempts have been made at a age and are less accurate than those of childre hear.

The earliest beginnings in speech have been at 18 months of age, but some of the children not begun to lip-read or to speak until after the 2 years. The rate and extent of progress have considerably. No doubt they depend in part parents as well as the child. Common sense, standing, and affection in the parents count than does a high standard of education or int ability.

A. B., who became totally deaf at 7 months, aft began to lip-read when he was 1 year and 8 mont and to imitate words spontaneously at 1 year a months.

C. D., first seen at 1 year and 8 months, severely from birth, started to lip-read a month after his had begun to offer him home training. At 2 years 2 months he was both lip-reading phrases and sen and spontaneously trying to repeat words.

E. F., first seen at 1 year and 3 months, born so deaf that her mother could not make her hear her began to lip-read after three months' training. At 2 and 5 months she could lip-read hundreds of phra words. At 2 years and 11 months she tries to imit word that holds her interest.

G. H., first seen at 2 years, born deaf, has had conti home training. He did not begin to lip-read until h 3 years and 3 months old, and so far has only im approximately and used spontaneously "*Thank you*" "Goodbye."

The benefit of this early training is threefold. Fi the child's personality is extended through a wide and deepening of the child-parent relationship. The in the early stages the child's vocabulary is very limi the kind of training provided brings parents and into an ever-closer relationship and helps to build in the child a confident attitude towards normal contacts. By contrast, if child and parents rely gesture as a means of communication, the isolatio the child from normal society increases with advan age. Secondly, as with the hearing child, the ana and synthesis involved in speech comprehension stim and enrich the child's mental experiences. Thi the normality of the home environment, as a p where everyone communicates by speech, is b conserved and established before the child goes school.

Both the beginning and the nature of the h training depend on the results of tests of hearing in the research unit. A graded series of tests with children aged from 4 weeks to 5 years has b described in detail elsewhere (Ewing and Ewing 1 1947).

From the results of the tests children are ult classified into three groups. Those to whom an u moderately loud voice at 3 ft. is audible are pa deaf. Those who respond only to a loud raised at 1 ft. are severely deaf. Young deaf children cannot hear a loud voice at 1 ft. must be treated totally deaf to speech. Home training is modified the needs of children in each of these three gr i.e., the parents aim at developing speech com sion in partially deaf children through hearing.

reading; in severely deaf children through lip- g stimulated by hearing; and in the totally ild through lip-reading alone. It is rarely possible h a conclusion about a young deaf child's capacity r as the result of tests made at one visit. Most 32 children already mentioned visit the clinic ically, and the parents come for guidance at r intervals.

EDUCATIONAL OPPORTUNITIES

er the Education Act of 1944 special educational ent of children handicapped by defects of hearing e begun at the public expense at the age of 2 years to be continued to the age of 19 years. In the capped Pupils and School Health Service Regula- 1945, provision is made for two groups of children mpaired hearing: (1) deaf children—i.e., "pupils ave no hearing or whose hearing is so defective hey require education by methods used for deaf without naturally acquired speech or language"; partially deaf pupils—i.e., "pupils whose hearing defective that they require for their education arrangements or facilities but not all the educa- methods used for deaf pupils."

Ministry of Education (1946) states that if with lp of lip-reading and/or the use of a hearing-aid tially deaf pupil can make satisfactory progress ordinary school he should remain there, but if difficulty in keeping his place in class he should a special school for the partially deaf where nous special education would be provided for him h the use of an appropriate hearing-aid combined ip-reading. The main problem, therefore, in ying a partially deaf pupil is to decide whether ll need part-time or full-time special educational nent. This problem can be readily solved by a of tests, together with the otologist's report and neral medical history. The tests include pure-tone metry, speech tests of hearing, and tests of educa- achievement and of mental ability. The giving se tests presents little difficulty with pupils aged rs or more. With children aged 5 years or younger factors must be taken into account. A pure-tone does not give the information that is most urgent a child of pre-school age. His capacity to hear h is the essential factor. At his age he cannot ven tests of educational attainment; nor can his rehension of language be assessed through reading. have therefore discarded the "tunnel test" with pure-tone audiometer (Ewing 1930) in favour of the of capacity to hear speech and other meaningful ds.

has been shown already that modern educational ment for a child with impaired hearing should be eded by suitable home training to the age of 3 or 4 s. Unless parents are qualified teachers of the deaf cannot convert their child's spontaneous imitations ords into intelligible speech; nor can they develop acquisition of language. Attendance at a nursery or school is therefore the next step. Here lip- ing and speech would be further developed and, never possible, stimulated by auricular training. er the child would proceed through the kindergarten he junior school. In a recent Medical Research ncil investigation (not yet published) the hearing of pupils in eight schools for the deaf was tested: had some useful capacity to hear speech with a up hearing-aid; and 144 could recognise called nbers, by hearing alone, with a degree of accuracy ying from 50–100%.

The application of scientific inventions in the form better hearing-aids and amplifying apparatus calls certain modifications of, and additions to, the older thods by which speech and language were taught as subjects in the school curriculum. But a deaf child's success in learning to talk intelligibly does not depend solely on his residual capacity to hear. Mental factors are also of great importance. Some totally deaf pupils acquire lip-reading and speech to a very useful degree. Speech becomes their first and principal language. In other cases, in spite of some useful capacity to hear, the best standard of lip-reading and speech of which a child is capable falls short of what is considered to be a "useful" standard. In any modern system of classifying the pupils within a school for the deaf account must be taken of two groups of children: (1) those who have some residual capacity to hear or who, in spite of total deafness to speech, can be enabled to communicate with ordinary people by speech; and (2) those who, with or without any capacity to hear speech, have proved to have little aptitude for learning to lip-read and to talk. These pupils are usually transferred to "silent" classes. Obviously the "silent" classes should not form part of the régime of an "oral" school. The needs of these less fortunate pupils are not negative but very positive. They require a different kind of educational treatment and environment, through which opportunities for the development of personality and of their practical and mental abilities are provided. At present the needs of this group of children are a matter of concern to teachers of the deaf and to those responsible for the organisation of special schools, most of which have, until now, been constituted on an all-age basis for the education of pupils with defective hearing of all types other than the ineducable. It is now hoped to allocate to certain schools responsibility for children belonging to specific categories. This is the only means by which the educational needs, characteristic of different age-groups, can be given the practical recognition that they already receive in the case of ordinary children. This reorganisation already includes provision for grammar-school education for pupils of superior ability. There should also be separate schools for the deaf who are incapable of oral education. It is contrary to their interests to remain as a minority tacitly, if not explicitly, recognised by their fellow-pupils and teachers as inferior in educability and status

NEW PROSTHETIC EQUIPMENT

Recently we saw in New York a demonstration of the equipment developed in Bell Telephone Laboratories to make speech visible while it is being spoken. The equipment includes a cathode-ray translator. Patients without hearing, one of them a member of the staff of the laboratories and two senior pupils of the Lexington Avenue School for the Deaf, were able to converse, relying for speech reception solely on luminous patterns seen on a moving screen.

Before being trained to recognise sentences and words symbolised in this new way all these patients had acquired speech and were accustomed to ordinary reading. It is doubtful whether, in its present form, the visible-speech apparatus could help deaf children while still in the early stages of gaining their first experience of words.

It has been stated that, when trained, a deafened adult can follow visible speech more easily than he could lip-read it. But lip-reading has the advantage of being a form of direct and personal contact.

Apart from its use as a way of communication the new equipment is likely to prove a means of teaching children to speak more normally when they have never heard and are severely or totally deaf. Ordinarily the accuracy and skill with which they talk are based on tactile and kinæsthetic sensations arising from the movements of the organs involved and contacts of the tongue and lips. With the visible-speech apparatus they can see in detail the sounds they make while they are talking. They can learn to compare the visible recordings of a word or phrase spoken by the teacher with recordings of their own efforts. The patterns are detailed and remain on the screen long enough to allow a second glance. From the deaf pupil's point of view they can give him the best means of expressing both his own speech and the speech of others in terms of a single medium. An extended investigation into the educational possibilities of this invention is now being made at the University of Michigan, where a special organisation has been set up. As yet the equipment is exceedingly complex, very costly, and large.

Among devices that indicate in a readily recognisable form certain of the variations and characteristics of speech one of the most promising is the pitch indicator. The sound of the voice causes thyratron valves to glow. Raising the pitch of the voice increases the number of valves lit up. The apparatus can be adapted to indicate changes in pitch corresponding to those of musical notation. In the hands of a skilful teacher trained to use it a pitch indicator is attractive to deaf children. It seems clear that, when using it, a pupil with suitable aptitude can learn to adjust the pitch, loudness, and duration of his voice (Sterne and Zimmermann 1939, 1940.)

For many children with defective hearing and for deafened adults hearing-aids constitute the most important form of prosthetic device. The incidence of partial deafness among school-children is considerably larger than that of severe or total deafness. Improvements that have taken place since 1939 in the design of hearing-aids for individual use are very great (Ewing 1947).

Efficiency in the fitting of aids is much enhanced if a hearing-aid evaluator is employed. This type of equipment has been designed and used for some time, with conspicuous success, for investigations under the Medical Research Council in England and for the National Research Council in the U.S.A. The accuracy with which speech is received by a child or adult using a particular hearing-aid can be tested and compared with the reception ordinarily possible to the patient listening without an aid.

AURICULAR TRAINING

Greater even in importance than these technical advances is the significance of new conceptions of auricular training and of the use of aids as a factor in personality adjustment. It is in terms of personality as a whole that success in the application of prosthetic devices in special educational treatment must be judged. Selection of an aid whose capacity to reproduce speech and music is suited to the individual child or adult is the first step. Training in its use should be associated with the acquisition of skill in lip-reading. For the present, at any rate, an efficient type of group aid gives the best introduction to amplified speech. Considerable individual variations in initial capacity to tolerate loud sound are found among most classes of children who are partially deaf (grade II) or who have useful residual capacity to hear (grade III). If trained in this work, the teacher can ensure, with a group aid, that the volume of sound delivered to each pupil is correctly adjusted. Speaking like a good radio announcer in a manner that combines clarity with naturalness, at an even level of loudness and at a short distance from the microphone, the teacher makes sure that the sound input to the aid is uniform. He can then guide each pupil to a correct adjustment of his volume control.

Since group aids can reproduce speech very accurately and at high levels of loudness, they will probably remain the best form of aid for use in the class-room, school assembly, or concert hall by children whose deafness is at all severe. Preparation, while still at school, for the use of individual aids in employment and at leisure is practicable for many and constitutes an

Recent investigations have shown that some and adults who, unaided, would be unable to loud speech 6 in. from the ear can, through acquire such skill in auditory discrimination and capacity to tolerate loud sound without other ill effects that the daily and continuous an individual aid is invaluable. If perceptive extensive, the aid is an excellent ally to lip Where deafness, though severe, is mainly the patient relies a good deal on lip-reading more on speech heard through his aid.

Programmes of auricular training should gradual initiation into the effects of hearing a noise and much experience of listening to speakers in variable acoustic conditions. F deaf patients the use of most types of aid in life is only efficient if they frequently adjust the control, which may be supplemented by a designed to modify tonal quality and the of general noise background.

Many boys and girls whose opportunities of sound would otherwise be very incomplete, gible, can now have auditory experience the of which is taken for granted in ordinary schools. spoken word, in its richness and variety, take place as the supreme form of stimulation to relationships and mental growth. There is no ind that absence or loss of auditory acuity involves of capacity for musical appreciation. The sing the choir of the Royal Schools for the Deaf, Manc in the British Council's sound film *Education of t* exemplifies what has already been proved pos certain progressive schools in Britain and the U.S. the Maud Maxfield School for the Deaf at S several generations of pupils have now benefited training in which piano music and a percussion are used to promote rhythm in movement and spe

To complete the process of adjustment to their cap, school-leavers who use aids need simple and pr courses of instruction in the care and managem their instruments, the mechanism of hearing, elementary phonetics, with vocational guidance. vision of aids and auricular training and instructi lip-reading should not be restricted to pupils wh educationally retarded through the handicap of de Deaf and partially deaf pupils of good or superior and achievement are equally entitled to these for special treatment.

SUMMARY

It is now possible to develop speech comprehe through lip-reading in deaf children under 2½ ye age with the result that some of them make spont *attempts to talk.*

Such training should be begun at the age of 6 m or as soon as deafness is discovered.

Successful learning is essentially spontaneous satisfies the needs of the personality as a whole therefore as much emotional as intellectual.

The type of home training depends on the classific of degree of deafness by tests.

The provisions made by the Ministry of Educ for the training of deaf children are detailed.

New hearing-aids are described, including visible- apparatus.

RCINOMA OF THE ŒSOPHAGUS AND UPPER STOMACH

PROFESSOR GARLOCK'S ADDRESS

AKING at the Royal College of Surgeons of England t. 16, Prof. John A. Garlock, New York, recalled he first successful œsophagectomy was performed eek in 1918. The preceding twenty years had seen preliminary work on the surgery of the upper ch. notably by Bilroth and his associates. Between and 1936 little progress was made. but in the last years there had been considerable advances which tributed to four factors: (1) the development of n endotracheal anæsthesia: (2) technical advances raumatic surgery with minimal blood-loss. free ne, and accurate suture methods; (3) a proper standing of the physiology of chest mechanics: and e advent of penicillin and the sulpha group of drugs. fessor Garlock emphasised that any patient ted of having carcinoma of the œsophagus should bmitted to œsophagoscopy. The barium swallow not be relied on in early cases, and conversely diological diagnosis of carcinoma had on occasion disproved by the œsophagoscope. All carcinomas ating in the œsophagus were squamous; these nous carcinomas never spread into the cardia. h they very commonly involved glands below the ragm. particularly the paracardial group. On ther hand. the adenocarcinomas originating in the ch often spread into the œsophagus and might as high as the aortic arch. The squamous variety not metastase early. but they quickly became able through invasion of neighbouring structures. ccessful handling of these cases depended on team- and on careful preoperative preparation to correct hydration. avitaminosis. disturbances of protein olism, and variations of mineral metabolism were commonly present. He liked his patients to weight while in hospital awaiting operation.

to three years ago all resections for carcinoma of wer œsophagus and upper stomach were performed gh a transthoracic approach. This had the serious back that operability was not determined until xtensive exposure had been completed, for only then the subdiaphragmatic glandular field be examined. ld the growth prove to be irremovable, the patient been subjected to a useless traumatising procedure, he surgeon to a disheartening waste of time. Accord-, Professor Garlock had evolved his combined minothoracic approach.

patient was placed on the table in the right lateral ion. The first stage was a high left rectus incision at the r border of the muscle; if exploration of the abdomen ed the growth to be inoperable, then the incision could apidly closed after performing a gastrostomy. If the th was operable, then the incision was extended into the ntercostal space after division of the 8th costal cartilage r as the posterior scapular line. and completed by splitting iaphragm to the hiatus. This incision gave an excellent sure, and through it total gastrectomy and partial reatectomy could be carried out with the greatest ease. absence of postoperative pain, which was a notable ure, was probably due to avoidance of rib resection stomach was mobilised by dividing the left gastric artery freeing as much of the greater curvature as was necessary. vided the gastro-epiploic arch on the greater curvature maintained intact, there was little danger of necrosis of stomach wall through poor blood supply; he had seen this nly 2 of 100 cases. This degree of mobilisation would mit the stomach to reach to the thoracic inlet with ease without tension. Two rows of interrupted silk sutures ch must never be under tension. were used throughout anastomosis to the œsophagus. The stomach was pared for anastomosis by removing a circular portion the of the œsophageal opening, and clamps were never used operation was completed by drawing the stomach up r the œsophagus and anchoring it by interrupted sutures both mediastinal pleuræ. Very careful suturing of the phragm to the stomach was necessary; 2 cases had been t through herniation round the stomach. The intercostal ision in the chest was closed by interrupted silk sutures, ter inserting an under-water seal-drain through a dependent intercostal space. If necessary, a jejunostomy could be done before closing the abdominal incision.

After total gastrectomy the digestive upsets that followed the use of a long loop of intestine were avoided by isolating a segment on the Roux on Y principle for anastomosis to the œsophagus.

For carcinoma of the middle third Torek's operation had been routinely performed until three years ago. Despite some successful results (1 patient was alive and well twelve years later) it was a bad operation; with it the subdiaphragmatic lymph-glands were not removed, and patients were not comfortable. He did not like skin tubes, and he had had no success with a subcutaneous segment of intestine. as described by Yudin. He considered that removal of the œsophagus should be undertaken only if immediate restoration of continuity could be effected. For these difficult middle-third tumours Professor Garlock used the same left-sided incision and dislocated the œsophagus from beneath the arch of the aorta. He had not found this manœuvre difficult, but it was important to avoid injuring the intercostal arteries and the thoracic duct. This could be avoided by keeping close to the œsophageal wall; and if local spread of the growth rendered this impossible he considered the case inoperable. Surgeons in Britain preferred an approach through the right chest, but he found it difficult to stage the procedures. Time would show which of the two methods was the best.

Carcinoma of the upper third was fortunately very rare, as it quickly became inoperable. He had recently removed one such tumour, the anastomosis of stomach to œsophagus being completed through a separate cervical incision after mobilisation through the chest. This patient had died in a vasovagal attack, caused by the division of both vagal nerves: this unfortunate end result could be prevented by preoperative atropinisation.

Professor Garlock had not performed any palliative short-circuiting anastomoses, since he felt that the high mortality-rate would bring the surgery of œsophagus into disrepute.

In 220 cases explored by him for carcinoma of œsophagus and upper stomach, approximately 50% were operable: and the operative mortality was 28–30%. The oldest patient was 79 and the youngest 30; the average age was 60+. Of those patients who survived operation, 32 were alive and well—1 twelve years, 1 eleven years, 12 over five years afterwards, and the rest for shorter periods.

STUDENT AND TEACHER

In his inaugural address at the Westminster Hospital on Oct. 6 Sir ADOLPHE ABRAHAMS expressed sympathy with the students who regard lectures as a waste of time; only too often, he said, lectures are no more than an articulate textbook for which indeed a gramophone might be substituted. Yet he held that they have a legitimate place. Teaching is not merely intended to inform students of facts; it should aim at educating the judgment and at direction. The student should disabuse his mind of the idea, only too prevalent, that a lecture is there simply to save him from taking trouble: it should teach him how to take trouble, and perhaps save him from unnecessary trouble. The diversity of opinion in the medical schools is illustrated by the provision, which ranges from many hundreds of lectures to none at all; and although Sir Adolphe himself favoured the principle of allowing attendance to be optional he realised its impracticability, quite apart from the doubt whether a young man is a reliable judge of what is good for him.

The more important subject of clinical instruction, he continued, represents the art as well as the science of medicine. The teacher has a dual responsibility—to help students to pass examinations and simultaneously to make them capable practitioners. These two undertakings, while to some extent inextricably associated. are by no means the same thing. No amount of training can make a man clever, but almost anyone can be trained to be capable; and while we admire the clever doctor it is the capable man who is valued. Whatever their shortcomings in the matter of lecturers, British schools of medicine can proudly and confidently claim to give the best bedside instruction in the world and to produce the best general practitioners in the world.

He distinguished three methods of approach: the didactic method; the Socratic or catechistic method; and a third which might be described as the "personality" method, which is seen on rare occasions as practised by a man of great experience who may or may not be learned but is certainly wise. He says but little; he asks few questions or none at all; but he creates an atmosphere through which there is a subconscious registration by the onlookers of his mental processes as well as of his attributes. The didactic method is attractive to both student and teacher but the catechistic is the more valuable. It is a heavy strain upon an instructor compelled to work at high pressure for 60 minutes in the hour to keep everybody continuously on their toes.

Education at the bedside may conveniently be summed up as Bedside Manner—a term which at its best is generally the subject of more or less good-humoured banter and at its worst is employed with a sneer as if it were something sinister or opprobrious. Yet Bedside Manner comprehends the relation between patient and doctor and comprises very many things. The qualities of kindness, sympathy, gentleness, and the capacity to inspire confidence are natural or quickly acquired by some and with difficulty by others; but contact with disease, with mental and physical suffering, develops them to a greater or less extent in all, and success in practice is proportionate; so we are not surprised to find one, although academically undistinguished, so eminently successful, and another, a brilliant gold-medallist, so dismal a failure. This education is continuous throughout the whole of professional life, but the foundations are laid in the medical school. One learns to suffer fools gladly; still better to realise how often we, not our patients, are the fools; to disagree without being disagreeable; to listen to the most preposterous nonsense with an unmoved countenance; at times to act as the confidential family lawyer; at times as a priest to hear confessions; to learn that in life if not in logic there are degrees of truth, and that it is not through a knowledge of anatomy that one reaches an understanding of the human heart; to appreciate that the democracy of disease puts duke and dustman on an equality when in a sick-bed, so that we are as much at home with the highest as the lowest are at home with us. All of this surely constitutes Bedside Manner—a term that should be regarded with respect and not with the suspicion and contempt that is so habitual.

There are unfortunately many things that cannot be learnt in hospital, and the old apprentice system had much to recommend it. What a privilege it must have been for a young man to accompany a good old-fashioned general practitioner on his rounds. He may not have been taught the differentiation of myasthenia gravis from bulbar palsy or how to diagnose an obscure case of periarteritis nodosa; but he may have learned how to deal with a baby's bellyache, or how to handle miserable poverty-stricken senility, and many other things that are not in the medical curriculum.

HARVEIAN ORATION

THE annual Harveian Oration was delivered on St. Luke's day, Oct. 18, at the Royal College of Physicians of London, this being the 291st occasion of its delivery. The orator was Dr. C. E. Lakin, consulting physician to Middlesex Hospital, who chose as his subject Our Founders and Benefactors. Recalling that the college was founded in 1518 by Henry VIII at the instigation of one of his physicians, Thomas Linacre, he said that Linacre was one of a group of men including Grocyn, Dean Colet, Sir Thomas More, and Erasmus who were profoundly influenced by the Revival of Learning, in the doings of which they took an active part. The foundation of the college and the revived interest in medicine were the direct result of that remarkable mental awakening.

Among the benefactors mentioned were John Caius, who was among the first to introduce the study of practical anatomy in this country, and William Gilbert, physician to Queen Elizabeth and James I. Dr. Lakin pointed out the three stages in the evolution of knowledge as exemplified by these investigators. Linacre looked to the past and recaptured the knowledge of and the old philosophers: Caius was deeply in the same learning but turned to the practical tion of nature; while Gilbert steadfastly looked and by introducing the experimental method research may be said to be the first English scientist.

MENTAL HEALTH WORK IN A

DR. FRANK FREMONT-SMITH, medical director Josiah Macy Jr. Foundation of New York, ad meeting at Manson House, London, on Oct. 17, the Armed Forces came to realise during the much more could be achieved by the psychot team, made up of psychiatrist, psychologist, and atric social worker, than by any of these working In the United States the ideas and enthusiasm in the Services had borne fruit in the Veterans' tration, which was now putting into effect a t and training programme which would have an effect on the mental health services. One effect, had been to attract many of the better people a the State mental hospitals, where pay and not as good or the work as vigorous as in the V Hospitals: consequently the mental hospitals deteriorated in their nursing and medical staffs, t overcrowded, and the exposure of their defects in newspapers had shocked many people, though it be necessary to bring the facts home to the State latures and create a very strong public demand for before effective measures were likely to be underta

The proper functions of psychiatric social worke become a subject of controversy, since, in areas i south and west where psychiatric services were these workers had taken on duties which would regarded as part of their legitimate job in the States. A similar dispute had centred on the ri the clinical psychologist to practise psychotherapy. Fremont-Smith inclined to the view that the doctor or not, who had been trained by a psychothe was the right person to give psychotherapy. The discussion of problems affecting human relations be carried out by psychotherapists, psycholo psychiatric social workers, cultural anthropologists, sociologists. Groups of 15–20 such people, meeti intervals for two or three days at a time, develop understanding which grew from their converging different standpoints. This was plain when such a was asked to consider a problem like world citizen Psycho-analysis had come to play an increasing par the training not only of psychiatrists but of pædiatric and general physicians. A psychiatrist seeking a pr sorial appointment would have to show outstan qualities to compensate for the lack of a personal psy analysis and the related analytic training.

Dr. Fremont-Smith said it had been very encour and impressive to him to find the progressive achi ments here of multidisciplined discussion at Roffey and the Tavistock Clinic; these developments co sponded very closely to his own view of what was requi nuclei of subtle and penetrating thinking are very im tant at this crucial point in world history. Psychi insight cannot yet, however, solve the major probl It is necessary therefore to make a long-range program building atom-smashers against hostility and aggres and thus releasing the nuclear energy of goodwill coöperation available in groups. (Dr. Fremont-S attended the Operation Crossroads at Bikini as official observer.) To a question whether such e could avert "the next war," Dr. Fremont-Smith a guarded reply, but said that when he was being psy analysed he had realised that he had hatred for pe he thought he loved and that this had set him thin about ways of diminishing hatred and aggression. it was unfortunately impracticable to have everyb psycho-analysed, he thought a most useful begin could be made in the nursery schools where the yo mothers and the teachers could be reached; but might take three or four generations to be effective. hoped that a new International Committee for Me Health might be formed next year, which would b body with close ties to UNESCO and the World He Organisation.

In England Now

unning Commentary by Peripatetic Correspondents

E first thing that impresses one in the American al schools is the tremendous energy the students nto their notes. Ward teaching rounds are not a inent feature over there (some of us in London this ner wished there were not so many of them here). aing is done mainly in "clinics," of which there cores. Some are for the staffs of different departs meeting together, some for the whole staff of one tment, some primarily for the interns (housers), and some for students. The students' notes be called for at any of these clinics, and at the s for students they are presented by themselves. student will usually recite the whole history and e of the case with tremendous detail of pathological tigations entirely from memory. So complete is "work up" that the teacher may be hard put to another facet requiring elucidation. The standard te-taking puts us very much to shame. But there ething impersonal and perhaps a little too academic esenting a case in this manner to a big class. It be a good method with postgraduates, but in spite weariness I prefer our ward rounds.

e cannot help being struck by the great part played athological investigations. and the rather advanced e of the surgery at many of the schools. This also s the teaching rather academic. The students attend the operating-rooms. In some operating s visitors (at any rate) are kept in a balcony partly mpletely shut off with glass screens. Opera glasses rovided and it is possible to see quite clearly what ng on but one is apt to miss what the surgeon is in spite of a microphone. When one asks the nts why they do not attend the operations they hey are too busy attending clinics or writing notes. y of us here feel that long hours spent in the operating-tre have little educational value, but it seems to me rtant that the student should follow his own case he theatre, imbibe the theatre atmosphere, and me familiar with the common surgical procedures— to mention the heavy responsibility he bears in y London teaching hospitals, where the student rd-clerk's" notes are often the only complete record he case.

t the medical schools I saw in America the whole ical training occupies but four years, and since there summer vacation of four months it is a little difficult understand how the necessary knowledge is obtained. eight months remaining are divided into four rters of two months each, with no apparent breaks. intensive programme is laid out for each of these uarters," with a certain amount of spare time for ding—more in the later years. This rather concented teaching must demand a high degree of application, d it would be my guess that a little inattention might ve rather large gaps in knowledge. But it is only to point out that at most of the schools only graduates arts or science are admitted, which presupposes a her older student, with some experience of methods study. Perhaps this is how they manage to learn much in such a short time.

* * *

I had imagined in my innocence that income-tax was graded as to reduce us all to the same level, more or s, of austerity. But I was wrong, for there are evidently eerful spirits among us who do themselves fairly well. still keep long-standing accounts at some of the big ondon stores, but seldom buy anything, for I have money for luxuries and they seldom have any of the osaic things I should like. The last I heard from one these emporia last month was that I had a credit lance of one penny, and in this pleasant state of lmost complete neutrality I have remained happily ntil yesterday, when I received a document purporting show that I owed them £70 1s. 11½*d*. The first item n the list was "Wine £18." I decided to try to work ut the personality and habits of the person who had t mixed up with me. The last time I had tried to get bottle of sherry from this establishment was just efore VE-day, when they said they couldn't give me any because I had not been buying wines or spirits from them throughout the war. But this man—it must be a man, because there was "Cigars £1 8s. 2*d*."—had no difficulty, and ten days later he had had "Wine £15." Perhaps he was giving a party. because he had "Balls £1 5*s*.," though for what game was not specified. He spent 18*s*. 2*d*. on dog meal, which sounds like an animal-lover, and there was an item "Zoological £1 1*s*." He hardly sounds like a research-worker buying frogs, and the price does not suggest pedigree puppies or kittens, so he must have been buying goldfish or tortoises for his children. There were coffee spoons and several unspecified household articles, and "Handtruck £3 15*s*." which perhaps he uses for taking the wine away himself: it could hardly be for his wife to use when queueing, for no-one could get enough food at one time to need it. Lastly there was "A/c rendered" for £21 odd, so my unknown fellow-customer is perhaps rather happy-go-lucky, an extravert, a cyclothyme, a pleasing chap. As for the shop, I sent back the account with a few cold words.

* * *

Medical gentlemen engaged 120 years ago by the London (Quaker) Lead Company to look after their lead-miners, were given (Arthur Raistrick tells us[1]) a house rent-free, a salary, and an allowance for a horse. They were required to attend all the company's work-people and their families, whether they belonged to the workmen's fund or not, and by their contract of appointment were expected to work hard, well. and pleasantly. To an afflicted member of the fund they were to give a certificate at every visit, write the nature of his complaint on the sickness paper, and add dated reports of his progress. The instructions go on:

> "You are to visit personally, at their homes, the sick members, immediately you are required to do so, as it will occur that the progress of the fever may be arrested. and its otherwise regular course prevented by timely assistance
>
> "And in internal inflammation, so prevalent among the working classes, the important period of a few hours being lost for blistering or bleeding, fatal consequences ensue rendering all future attempts at remedying fruitless.
>
> "In case of accidents, also, the prompt assistance of a medical gentleman will, of course, frequently prevent after mischiefs and tedious complaints"

Even if his treatment for "internal inflammation" —probably lead colic—was unlikely to have the life-saving properties ascribed to it, at least it was to be given every chance. The doctor was also to advise patients on their regimen and was particularly asked to "prescribe, distinctly, *the hours of the day* during which it will really be beneficial for them to take the air."

> "And in your visits and intercourse with the members and their families," the injunction goes on, "you must bear in mind that not only prompt personal attendance, *but the highest degree of courtesy and kindness of manner* is requisite towards them, they being generally more susceptible to slights than persons of more liberal education, and of the higher walks of life.
>
> "Lastly the Court wish to impress upon you the consequences which must arise, if members (who are not apt to declare on the sick fund too early, but rather otherwise), be slightingly attended to, or a trifling medicine sent them by an assistant, or from neglect to label medicines with the proper directions. and not impressing on sick members the regimen to be observed, &c.—*diseases will be protracted, or disorders confirmed, to the danger of life*,—to the serious injury of the workmen's fund,—*and protracted attendance of the medical gentlemen themselves*"

What a discriminating use of italics!

* * *

"The incubation period," wrote a nursing orderly in the examination I set them, "is the time when the M.O. does not know the diagnosis."

* * *

Then there was the student who thought that regional ileitis was one of the likely snags in the National Health Service.

Letters to the Editor

WINTER IN EUROPE

SIR,—Sir John Boyd Orr said recently at Geneva that millions in Europe would be worse fed this winter even than during the war. We have our own difficulties, but comparing our lot with that of many thousands in Germany, Poland, Austria, Hungary, and Rumania, whose diet is little more than half of ours, we must surely feel that there is something, if only a little, which we can do to help.

Here I am appealing particularly for money for our European Relief Fund; for relief supplies, if they are to arrive in time, must be purchased soon.

Of the four beneficiaries of the fund, far the biggest amount is required by the Friends Relief Service for the purchase of food, clothing, and medicines for their work in Austria, Germany, and Poland. They could spend £20,000 on food alone immediately if they had the money: for such supplies, unsuitable for distribution in the normal ration, are still available in the sterling areas of the world. Smaller yet substantial sums are needed by the Ecumenical Refugee Commission for the household medicines they send to Germany and Austria, and for the work of German Educational Reconstruction in fostering the rebirth of democratic education in Germany. Finally, a comparatively small sum is needed for our own Supplies Fund to meet the costs of handling and shipping the food parcels and other supplies which we send to nine European countries—Austria, France, Germany, Greece, Hungary, Italy, Poland, Rumania, and Yugoslavia. Cheques and postal orders should be made out to "Save Europe Now European Relief Fund" and may be earmarked for any one of the beneficiaries listed above, all of which are registered war charities.

We shall also be grateful for help with any other of the needs listed in our circulated leaflet, which explains fully the ways in which help can be sent. The need is desperate: a few warm clothes, a little flour, and a bar or two of chocolate can make a tremendous difference to the lot of one of the many families who have to survive this winter on so little. We ask for help in giving practical expression to those Christian tenets of brotherhood and love on which our European civilisation is grounded.

Save Europe Now, HENRY CARTER
15, James Street, London, W.C.2. Hon. Treasurer.

VOLUNTARY INFERTILITY

SIR,—In his article on Oct. 11 Dr. Alex Comfort said that at the Camberwell childhood advisory clinics the reasons adduced for limiting the family "were strikingly uniform, war coming first, fear of renewed war second, and the consequences of war, particularly housing, third, followed by economic considerations."

There is, I suggest, room for doubt whether these are usually the true reasons for voluntary sterility. War, or the threat of it, or the perils and dangers of the world have been quoted so often in this context that they have become clichés—useful verbal masks behind which to hide one's real thoughts. To avoid parenthood because of these alleged reasons out of solicitude for the unborn may appear unselfish and even noble to some, including the potential parents themselves; but the facts, for what they are worth, are usually against this explanation of voluntary sterility.

Actual war conditions and a perilous state of non-belligerency (he would be a hardy optimist who called it peace) have led since 1941 to a continuously rising birth-rate; and even in the late 'thirties, when early war was becoming more and more certain, the rate tended to rise. Whether this increase was due mainly to the foundation of more families or to the birth of more children in families already existing is at present undisclosed. Clearly the former and more likely alternative is less significant of change in fertility habit since it is little more than a function of more marriages; but in either case no support is given to the "war and wretched world" argument. If it is antisocial to have more children, it is equally antisocial to have any children; but most married people do in fact have one or two children.

The underlying cause of voluntary infertility is surely the fashion of the times, which declares so many things to be more desirable than family life and has society in which a really large family is Economic factors reinforce and are reinforced by but as the standard of life declines and necessarily less artificial it may be that people, that they can avoid starvation, will be driven back and more to the basic natural satisfactions and families will become not only more frequent but in size.

Philosophically considered, of two evils it is people should avoid parenthood for the real because they regard children as a nuisance and economic drag—than because they think the bad a place to be born into. In this latter should be faced by an insidious defeatism and chæism that boded even worse for our country civilisation than the obvious facts allow.

Whitley Bay. JOSEPH V. W

EARLY RISING AFTER OPERATION

SIR,—In your leading article of Sept. 20 (you refer to our series of 629 surgical cases[1] in "early rising" was the routine. Since that was we have had another year's experience of early and nothing has occurred to alter our opinion. We found no disadvantages and our belief in its advantages is still further confirmed.

An outstanding fact is that no case of femoral th bosis has occurred in four years—i.e., in about 850 cases. This is perhaps the most concrete and obj feature and one which cannot be effected by fai gratitude.

Johannesburg. W. A. POCOC

ALKYLAMINE TREATMENT OF LEUKÆMIA HODGKIN'S DISEASE

SIR,—The article by Dr. Wilkinson and Dr. Fl (Oct. 11) gives ample food for thought. Of the 8 of myeloid leukæmia which they treated with alkyla 1 reached the refractory stage in twelve month another in six months; 1 showed no significant resp 2 were complicated by coexistent pernicious an and 1 showed a remission for four months. F there is claimed well-marked improvement; we are told how long the improvement lasted, but since authors state that they deal only with immediate e it appears to have been short. The 8th case lived months. In 4 there was no considerable increa survival (compared with untreated cases). Of th cases of lymphatic leukæmia, 2 needed blood-transfu after treatment. Of the 4 Hodgkin cases 1, which certainly advanced, deteriorated "in spite of" treatm For the others the most that can be said is that t remained satisfactory and without remission for sevent weeks.

The drug has "potent nucleotoxic and cytot effects," and unless treatment is controlled by d white-cell counts and bi-weekly full blood-counts, periodic sternal puncture and "various other hæm logical and biochemical examinations" there is a of aplastic anæmia, agranulocytosis, thrombocytop purpura, and severe aplasia of the bone-marrow, not mention nausea, anorexia, vomiting, diarrhœa, thrombosis at the site of injection. These many great dangers are hardly surprising in view of the that the substance used was originally intended for destruction of human life.

The results, which I think I have summarised fa should be compared not with those in untreated ca but with those in cases treated by X rays. With m therapy patients have a reasonable expectation survival for five years or more, in a state of modi comfort, happiness, and efficiency, with very little, any, constitutional disability and without furt interference beyond occasional blood-counts. By t standard the alkylamine treatment is a disastrous fail This, however, is not the view of the authors, for th are prosecuting their researches by new methods administration and control. In so doing they victims of the all-too-common delusion that because agency modifies the appearance of disease it must ne

RESTRICTING BOOK IMPORTS

—In my opinion your editorial last week on this
t is not strong enough. We *must insist* on a
e of opinion by the Board of Trade on this very
tant matter. At the present time I am engaged
ting a work on the life and writings of a foreign
I cannot obtain from abroad the necessary books
rence. This is, of course, no longer a free country:
rstand that the French, for example, are allowed
d by draft or cheque in francs at the officially
d rate of exchange any amount in payment of
published in this country. This utterly absurd
on is hampering progress in education here. Many
ooks as well as medical works, because of shortage
per (the Government seems to have plenty), are
f print. This is intolerable, and the situation is
ently getting worse. Why do we sit down to all
e restrictions ? We must fight for our rights and
our liberty, otherwise we shall go under. If these
s continue much longer the foreigners will take the
and the Britisher will be completely ousted. Let
therefore, adopt the fighting spirit, instead of the
p-like attitude which means defeat.

burgh. JAMES BURNET.

RAVENOUS INFUSIONS AND MASTOIDITIS

R.—In reply to the correspondence which followed
earlier letter (Aug. 23) I should like to make the
owing points :

y main contention is that the injudicious use of intra-
us infusions results in overloading of the general circula-
, which entails similar overloading of the respiratory
ulation and predisposes to a primary respiratory infection
ot of course blood-borne from the gastro-enteritis. The
cted respiratory secretion can then gain access to the
oid antrum in exactly the same way as infected
itus may do. Such respiratory infections in cases of gastro-
ritis are in my experience on the increase, and where
oiditis also occurs the organism most commonly found
me has been the pneumococcus. In one case pneumococci
e grown from one antrum and *Bact. coli* from the other.
Infected vomitus may certainly be the occasional cause
mastoiditis in these infants. In my hospital, however, in
rs gone by all infants were fed lying down by means of
tle slings attached to the heads of the cots ; in those
rs our cases of gastro-enteritis were uncomplicated by
toiditis.

My argument is that a new method of treatment which
ay be valuable in itself has been converted into a menace
indiscriminate use. As an example may be cited the
e of an infant, aged two months, who was admitted
ith what was recognised as very mild gastro-enteritis.
n intravenous infusion was given, the child died, and
t autopsy the only lesion was œdema of the lungs.

Royal Alexandra Hospital
for Children, Brighton. MARY A. LESLIE-SMITH.

POLIOMYELITIS COMPLICATING PREGNANCY

SIR,—Mr. Maxwell and Dr. Willcox in their article of Sept. 6, included no examples of poliomyelitis with respiratory paralysis in pregnancy. The following account of such a complication in the eighth month of pregnancy may, therefore, be of interest.

A married woman, aged 30, and in the eighth month of her second pregnancy, took ill with malaise, nausea, and frontal headache on Aug. 29. Symptoms persisted throughout the next day. On waking up at 6 A.M. on Aug. 31, she noticed weakness of the left arm and right leg, inability to sit up in bed, and shortness of breath. About 8 A.M. the breathlessness had increased and she developed difficulty in swallowing. There was no retention of urine. She was admitted to hospital at 11 A.M. on the same day as a case of acute anterior poliomyelitis.

The patient, a cheerful, intelligent, well-nourished woman, was slightly cyanosed and intensely dyspnœic. The respiratory distress compelled a bolt-upright position in bed—even a semirecumbent position was intolerable. Practically no subjective relief was obtained from continuous oxygen (5 litres per minute by Tudor Edwards spectacles), although the degree of cyanosis was reduced. Examination of the central nervous system showed pronounced nuchal rigidity ; in the left upper limb there was severe paresis of deltoid and triceps, and slight paresis of biceps ; in the right lower limb there was almost complete paralysis of iliopsoas and slight paresis of quadriceps, hamstrings, and dorsiflexors of foot. No contraction whatever could be observed in any of the muscles of the abdominal wall or in the thoracic or lumbar components of erectores spinæ. Apart from slight movement of the lower ribs there was no evidence of contraction of the intercostal muscles, the respiratory effort consisting almost entirely of violent contractions of the accessory cervical muscles of respiration. Auscultation of the chest showed very poor air entry on both sides with a few coarse crepitations at each base. No cranial-nerve abnormality was present, and examination of the other systems was negative. As the diagnosis of acute anterior poliomyelitis was beyond doubt, the patient was not submitted to lumbar puncture—a procedure which would have added considerably to her discomfort.

There appeared to be a reasonable possibility that diaphragmatic function was retained and that it might be sufficient to restore adequate pulmonary ventilation if given scope to act ; the disease was advancing rapidly ; and the child was viable. It was therefore decided to evacuate the contents of the uterus in the hope that respiration would be eased and the baby would be saved. Rapid classical cæsarean section was performed with anæsthesia by cyclopropane and oxygen under pressure, and a live female child weighing 4 lb. 3 oz. was delivered.

On return to the ward the patient's colour was good, she was less dyspnœic, and some degree of diaphragmatic respiration appeared to have been restored. For these reasons it was decided not to place the patient into a Drinker respirator immediately, as had previously been proposed, but to observe her for a period on continuous oxygen. A further factor in this decision was the risk of inhalation of secretions and vomit to which an unconscious patient is exposed in a mechanical respirator. Respiration and oxygenation (as judged by the patient's colour) showed little change in the first two hours, both being reasonably satisfactory ; but by this time it was becoming obvious that the patient was not recovering from her anæsthetic. She now appeared to be practically comatose, with all deep reflexes absent and only a sluggish corneal reflex. A definite right-sided facial palsy was also noted at this time. The coma became progressively deeper, but respiration remained unchanged and cyanosis practically absent until a few minutes before death at 7.45 P.M., when the vomiting of "coffee-ground" material produced fatal asphyxiation. The baby is now 5 lb. 1 oz. in weight and is progressing satisfactorily.

In reviewing the case cæsarean section seems to have been almost in the nature of a post-mortem operation for the sake of the child. The patient should have been out of her anæsthetic within half an hour, but her condition steadily deteriorated and she never recovered consciousness. Operation would have been impossible under local anæsthesia as the patient could not breathe of her own accord when lying down. Whether the cyclopropane had any adverse effect on the already injured nervous tissue is debatable, but it was felt that cæsarean section was of no benefit to the patient whatsoever. The disease must have attacked all the vital cerebral centres and given the patient no chance of recovery. The only benefit was that a live child was obtained.

This case bears out the observations of Maxwell and Willcox, and also those of Kelleher (*Brit. med. J.* Aug. 23, 1947, p. 291). Another case treated by cæsarean section has been reported by Freeth (*J. Obstet. Gynæc.* April, 1947), but in this case an equally good result could perhaps have been achieved by vaginal delivery.

Ayrshire Central Hospital, Irvine.

RICHARD DE SOLDENHOFF.

CLINICAL FEATURES OF POLIOMYELITIS

SIR,—In the report in your issue of Oct. 18 of the proceedings of the section of epidemiology and State medicine of the Royal Society of Medicine on Oct. 6, I am quoted as saying "that the current epidemic of poliomyelitis differed from previous English experience of the disease in clinical features as well as in extent."

With regard to the first part of this statement my actual words were: "As far as my limited knowledge goes, with one exception to which I shall refer in a moment, the present epidemic has shown no clinical features that have not been encountered in previous outbreaks in other countries." The one exception to which I referred was an unusual form of ocular tremor with or without cerebellar signs, already the subject of two recent communications in your journal.[1] Reference to the classical descriptions of poliomyelitis and polioencephalitis by workers in America, Sweden, and Australia should convince us of the fact that, with the possible exception already referred to, the clinical features of this outbreak have all been previously described.

Middlesex Hospital, London, W.1.
DOUGLAS MCALPINE.

THE METRIC SYSTEM IN MEDICINE

SIR,—In his letter of Oct. 18, Dr. Breen objects to my recommendation that preparations for internal administration should be written as a single dose and the number of doses stated, his reason being that under the Dangerous Drugs Act the total amount of the drug must be clearly prescribed. In the prescription for diamorphine hydrochloride, 5 mg. for a dose, send 10 doses, the *total* amount of the drug is clearly prescribed; it is 50 mg. To quote from Hugh N. Linstead's *Poisons Law*:

> ". . . the regulation only requires that the prescription shall 'specify the total amount of the drug to be supplied.' It does not say that the prescription must contain the words 'total amount of A, x grains.' So long, *therefore*, as the total amount of drug to be supplied can be calculated from the particulars given on the prescription, the requirements of the regulation are satisfied."

Croydon.
HORACE FINNEMORE.

CHOLERA IN EGYPT

SIR,—In an annotation on Oct. 11 you discussed the possible path of entry of cholera to Egypt. As a matter of fact "the pilgrim traffic from the Mohammedan countries to Mecca" should no longer be considered a cause of spread of epidemics, because of the efficient quarantining of pilgrims before they go home. A cause till now neglected is the movement of troops, who may carry infection from one area to another, as they did in Egypt during the last world war, when there were outbreaks of malignant malaria (*gambiæ*), typhus, and relapsing fever.

As to the present cholera epidemic, the bringing of infection by pilgrims from Hedjaz is not likely, (1) because the time of pilgrimage to Mecca (Oct. 23) has not yet come, and (2) because the present epidemic has stopped the pilgrims going to Mecca from Egypt. There is, and will be, no pilgrimage from Egypt this year, apart from a small number who had already left Egypt before the start of the epidemic and who will remain in Hedjaz till November.

As to the facts which point to the infection by troops, the following may be given: you remark, "cholera's home is India." (2) An of cholera is now in progress in India. (3) During weeks preceding the appearance of cases in Egypt was active traffic of troops from India to camps occupied Suez Canal area (as announced by (4) The outbreak of the present epidemic Al-Korain village, which is close beside camps area, and contains 10,000 men who work in the

Leysin, Switzerland.
AMIN

*** Our correspondent renews the allegation movement of British troops has been res outbreaks of typhus, relapsing fever, and m Egypt. It is difficult to see why an army in typhus and relapsing fever have been almost non through the excellence of its hygiene control, be blamed for the spread of these diseases in a where they have long-been epidemic from time Nor do we know of any evidence that malignant carried by *Anopheles gambiæ* was spread in during the late war by troop movements, either air, or water. There is in fact strong presumptive that the tragic outbreak of malaria in Upper was similar to previous malaria epidemics in which are attributed to the well-known ten *A. gambiæ* at intervals to overflow its normal The suggestion that cholera was introduced into this year by troop movements from India seem break down on the fact that there have so far no cases of cholera among British troops in India those stationed or arriving in the Canal Area, or Middle East as a whole.—ED. L.

STREPTOMYCIN IN INFLUENZAL MENI

SIR,—In your issue of Oct. 18 (p. 593) you "supplies of streptomycin are still strictly limit unfortunately there is not enough to treat every tuberculous meningitis or miliary tuberculosis." same note you give a list of hospitals to which appli may be made for the treatment of influenzal men with streptomycin. Surely, this does not appear justified at present. Influenzal meningitis respo penicillin in adequate doses, as we have recently (*Lancet*, Aug. 2, p. 164). Nor can the use of streptomy in influenzal meningitis be justified on the ground clinical research, since adequate reports of its effic in this disease have already been published in the Un States.

It seems to me that present supplies of streptomy should be used for the treatment of as many case possible of the hæmatogenous forms of tubercul if a clinical trial is to be attempted against anot infection, this should be against sulphonamide-resist and penicillin-resistant bacteria, and not *H. influe* which is sensitive to penicillin in massive doses.

St. Alfege's Hospital, London, S.E.10.

THE BARBITURATES

SIR,—Your leading article last week draws atten to the perils of the barbiturates. It is a sad comment on our way of living that so much sedative should used by the nation.

Some cautious practitioners, you say, will only prescr enough tablets to total less than a fatal dose. Ab 20 grains of phenobarbitone is an average lethal do though much smaller quantities have been known cause death. It would be impossible for a busy doc to see, say, every week all his patients who took phe barbitone—to say nothing of the waste of patien time. I think unreasonable the implication that practitioner who prescribes larger amounts is incautio Practically, long-term prescription of barbiturates confined to phenobarbitone, for the use of other for implies that the patient needs further treatment or cl supervision. Phenobarbitone is mostly used for epilep for "*tension neuroses*" in the busy, overactive pers for some cases of peptic ulcer and hypertension, for so dermatoses, and for menopausal disturbances which not respond to replacement treatment. Also migr may sometimes be improved by sedation between attack

h cases there is little risk of deliberate overdosing patient is known to be well balanced.

he more severe anxiety states, and particularly in ed depression, there is a great risk of suicide, so must be care in prescribing barbiturates. But , dressing-gown cords, and coal gas are so readily ible that it seems supererogatory to hamper the iption of a useful drug by limiting quantities.

on Mount, Essex. GAVIN THURSTON.

Obituary

HUGH NASH BRADBROOKE

M.A., D.M. OXFD, M.R.C.P., D.P.M.

Hugh Bradbrooke, who was appointed to the staff Prince of Wales's Hospital, Tottenham, only a year 0 ago, took up psychiatry after long experience of al practice. A pilot in the 1914–18 war, he gained -class in natural sciences at Oxford and qualified 5 from the London Hospital. As a student he was nding—in integrity and humour as well as in —and while holding house-appointments and ng at clinical pathology he collaborated with Roaf in a paper on Hypochromatic Vision, and Clark-Kennedy and Owen in observations on CO_2 Muscular Exercise in Man. On the clinical side he arly interested in nervous and mental disorders, e was for a time assistant medical officer at Little- Mental Hospital and clinical assistant in the tment of nervous diseases at the Radcliffe Infirmary. d. He became M.R.C.P. in 1927, and while in practice nger carried out, with D. A. Mitchell, an investiga- into the use of quinine in normal labour. This ained him his D.M. degree in 1934, and in the ng year he and Mitchell recorded it in the *British al Journal.*

n after the outbreak of war Bradbrooke joined R.A.F.V.R., where he served as a neuropsychiatric alist with the rank of squadron-leader. On demo- tion he did not return to general practice but nued to work in his specialty. He was appointed nical assistant in the department of psychological cine at Middlesex Hospital and a neuropsychiatric alist to the Ministry of Pensions. On election he Prince of Wales's General Hospital he started a d-guidance clinic; but unfortunately he held his for only a few months before he was taken ill.

s high character and unselfishness," writes a col- ue, "made it easy to work with him; and his abilities e recognised by all the staff." A friend of Oxford days wise speaks of the quality of his mind, which was etty good if not actually first-class. If he did not, the conventional sense, fulfil early promise it was ably because his intellectual honesty would not w him to pursue the competitive way of life, the and thrust of which was not to his taste. For humbug its various forms he had a keen nose, but when he it succeed he was merely amused. Indeed he was rmined not to take life more seriously than it erved. As a young man he was gentle and sensitive, h an unusual power of insight into his own mind d those of others—a power that certainly did not inish with the years."

"The loss of Hugh Bradbrooke," writes another end, "will be a great blow to many who worked with m in the R.A.F. during the war. One knew he had d a distinguished career in general practice and in chiatry before the outbreak; but to work with him d see him in contact with Service people, especially in handling of aircrew personnel, was to learn how ilful, patient, kindly, and sincere he was. To me he presented the kind of physician who was so beloved an earlier generation and who could be utterly depend- ble; and yet he fulfilled the requirements of a time hen youthful thought, vigorous action, and decision, ith the wisdom of the older school, were so valuable. e knew his subject, which was to treat cases of flying tress, because he had himself flown as a pilot and later ad crashed and injured his spine in a glider accident: o better person existed to treat stressed aircrew. Out- de his work he could be genial and enthusiastic at games or social activities connected with the unit, and was at all times a cheerful companion.

"He will be much missed. No-one could fail to be impressed by his gentle kindliness, and wide culture, and by the courage with which he fought his affliction in the last two years."

ERNEST ARNOLD HODGSON HINDHAUGH

M.B. LOND., F.R.C.S.

Mr. E. A. H. Hindhaugh, who died on Oct. 9 at Ruthin Castle at the age of 42 after a long illness, qualified from the London Hospital in 1928, and took his M.B. the following year. After holding house-appointments at the London, the Royal Cancer Hospital, and the Royal Hospital, Wolverhampton, he worked in Liverpool as visiting assistant surgeon to Mill Road Infirmary until September, 1939, when as surgeon lieut.-commander R.N.V.R. he became surgical specialist in H.M. Hospital Ship *Amarapoora*. The work of turning his department into a first-class surgical unit he described admirably in the *Royal Naval Medical Journal* in 1942. His health began to fail in 1944, and he was invalided from the Service, but he returned to Liverpool full of zest to rejoin his old hospital, now moved to Broadgreen, and though a sick man he continued to do a full operating list to within a few months of his death.

"A hard-working general surgeon, Hindhaugh became a landmark at Scapa," writes C. A. C., "for he was well suited to deal with the emergencies which occurred in the Home Fleet in the early days of the war. His judgment was exceedingly sound, and like all good surgeons he never operated unless he must. But once he had decided on surgery, he acted with great boldness, and had a knack of knowing just how much a patient could stand. He added greatly to the pleasanter side of ship life by his magnificent baritone voice, and his classes to naval ratings on the appreciation of music were always packed."

DR. COURTNEY GAGE

R. M. writes: So many years have passed since my first meeting with Courtney Gage that the memory has faded, but it probably differed little from a thousand later occasions. A wonderful friendliness, perfectly frank and unstudied, was so characteristic of him that it was the easiest thing in the world to like him, and as time passed to become more and more fond of him: and so everyone found it. Nor did it take long to realise that his kindliness of heart showed itself habitually in acts of generosity. No-one could have given his help more freely and willingly in cases of urgency and difficulty, and no-one could have had a less mercenary view of his life's work. It is small wonder that Gage earned universal respect, admiration, and friendship.

Ilford

The straightforward simplicity, which gave his character its great charm, becomes all the more attractive when his career is recalled. With whatever degree of determination Gage started out in 1919 to become a radiologist—to have to go back to pass a preliminary examination, to turn student at 34, to qualify in five years, and two years later to be elected honorary assistant radiologist at St. Mary's—all shows gifts and intelligence of a high order. In a lesser man such rapid promotion and success might have led to some show of self-satisfaction; but in Gage there was no trace of it. He was always ready to give his fullest help, but that his opinion had the great authority which it undoubtedly possessed seemed altogether absent from his mind. His exceptional talents led him to a prominent position in his own specialty, but his chief appreciation came, as was proper, from the St. Mary's honorary staff. To feel that at the back of all one's work there was his invaluable help to be had for the asking was a real satisfaction, and to have him as a friend and colleague was indeed a privilege.

Public Health

Food-poisoning in Northamptonshire

At the end of last month there was an outbreak of illness, with diarrhœa and vomiting, at the village of Little Houghton, Northamptonshire. Of a total population of 416, 133 were affected, most of these falling ill on Saturday, Sept. 27, or Sunday, Sept. 28; there was 1 death. Specimens of fæces from 3 patients on Monday, Sept. 29, contained salmonella organisms, which were later identified as *S. dublin*.

Milk was supplied from a single farm to all but 25 of the village's residents; and none of these 25 fell ill. Inquiry at the farm revealed that on the previous Thursday, Sept. 25, a 2$^1/_2$-year-old heifer had been suspected of having a "chill"; the heifer had calved prematurely a fortnight before. Milk from this heifer was not included in the bulk supply after Friday, Sept. 26, but the animal was not isolated from the herd. It died on Saturday, Sept. 27, and the carcass was removed to a knacker's premises, where it was apparently cut up, boiled, and sold at once, for no trace of it could be found at 4.30 P.M. on Monday, Sept. 29. Workers at these premises reported, however, that the udder was badly bloodstained.

Samples of the milk delivered on Sunday, Sept. 28, and Monday, Sept. 29, contained no pathogenic organisms. On Tuesday, Sept. 30, a veterinary surgeon from the animal health division of the Ministry of Agriculture found on inspection that one cow in the herd had acute mastitis, while a further two were suspected of having this condition; but samples of milk and fæces from each cow in the herd did not reveal any salmonella organisms. The cow with acute mastitis was removed from the herd, and pasteurisation of all milk was instituted.

Cut in Milk Priorities

Last winter's severe weather, and this summer's drought, have together reduced the home production of milk by some 30,000,000 gallons, compared with last year. This fall has made it impossible to build up sufficient stocks of dried milk for baby-feeding to last through the winter. It has therefore been made an offence to use such dried milk for purposes other than feeding babies, a tempting thing to do now that household dried (skimmed) milk is no longer obtainable.

A more drastic measure came into force this week, when priority allowances of liquid milk were reduced as follows:

Invalids.—Allowances reduced by two-sevenths, so that conditions in class I qualify for 10 pints a week instead of 14, and those in class II for 5 pints instead of 7.

Children Aged 1–5 Years.—Weekly allowance reduced from 7 to 6 pints.

Non-priority Catering Establishments.—Reduction of allowance by a quarter, bringing the hotel resident into line with the normal adult consumer.

Cholera in Egypt

The cholera epidemic in Egypt continues to spread. Reports in the *Times* show that the daily total of deaths rose from just over 100 at the beginning of last week to more than 550 at the beginning of this week, when about 1000 new cases were being notified each day. Up till the beginning of this week the epidemic was still centred on the area north-east of Cairo, where it started: Cairo and Alexandria were only slightly affected, but infection had spread into Upper Egypt, which had hitherto been untouched.

Half a million people are being inoculated daily with vaccine presented by Britain, the United States, Iraq, France, Brazil, Tunisia, Italy, Switzerland, Iran, and Russia. The World Health Organisation's expert committee on quarantine, meeting in Geneva this month, agreed that the question of vaccine potency should be referred to a committee on biological standardisation. At this meeting Dr. Mohammed Nasif Bey said that the epidemic was limited more or less to rural areas. Egypt, he added, needed a hundred more ambulances to carry cases and suspects to hospital.

The Egyptian authorities, according to a correspondent, have been impeded by the movement of people out of the infected areas. cautions in other countries include the est by Palestine of quarantine posts at its frontier, stringent measures of control at French Med ports; all dock employees at Marseilles who come into contact with ships arriving from Egypt been vaccinated.

Poliomyelitis and Polioencephalitis

The decline in notifications of poliomyelitis 338 and of polioencephalitis 26 (27) continued in the ended Oct. 11. Figures for the previous week are in parentheses. In London notifications were: myelitis 31 (38), and polioencephalitis 3 (3). There substantial declines in notifications of polic Bedfordshire 3 (10), Durham 5 (14), Essex 7 Lancashire 43 (64), Middlesex 17 (28), and Yorks, Riding 11 (18). The most important rise was in shire 13 (5).

Two large-scale inquiries concerning poliomye known to be in progress. One, from the Health, derives its information from certain infe diseases hospitals and general hospitals throughout country and aims at securing more accurate of the fatality and severity of the disease in the epidemic. The other and more comprehensive organised by Dr. A. M. McFarlan and other member the staff of the Public Health Laboratory Service, concerned with the epidemiology of the disease in sele areas. Although these two inquiries are separate, method of tabulating cases is almost the same for

Infectious Disease in England and Wales

WEEK ENDED OCT. 11

Notifications.—Smallpox, 0; scarlet fever, whooping-cough, 1043; diphtheria, 201; paraty 12; typhoid, 8; measles (excluding rubella), pneumonia (primary or influenzal), 403; cerebros fever, 45; poliomyelitis, 338; polioencephalitis, encephalitis lethargica, 2; dysentery, 67; puer pyrexia, 106; ophthalmia neonatorum, 71. No of cholera, plague, or typhus was notified during week.

Deaths.—In 126 great towns there were no de from scarlet fever, measles, or diphtheria, 2 (0) fr enteric fever, 8 (0) from whooping-cough, 70 (4) fr diarrhœa and enteritis under two years, and 13 from influenza. The figures in parentheses are those London itself.

The number of stillbirths notified during the we was 216 (corresponding to a rate of 23 per thous total births), including 30 in London.

Births, Marriages, and Deaths

BIRTHS

Beaton.—On Oct. 17, at Dumfries, the wife of Dr. D. R. Beato a daughter.

Bell.—On Oct. 14, at Newcastle-on-Tyne, to Dr. Jean Bell (Cass), wife of the Rev. R. G. Bell—a son.

Dickson.—On Oct. 17, at Nunthorpe, Middlesbrough, the of Mr. D. C. Dickson, F.R.C.S.E.—a son.

Figgis.—On Oct. 16, at Harrow, the wife of Dr. M. M. Fig a daughter.

Gibbs.—On Oct. 14, at Cobham, Surrey, the wife of Dr. A Gibbs—a son.

MARRIAGES

Scrivener—Compton.—On Oct. 15, at Chichester, John Scrivener, M.B.E., captain R.A.M.C., to Patricia U. Compton.

DEATHS

Dodds.—On Oct. 15, at Edinburgh, Mary Janet Dodds, O L.R.C.P.F.

Houghton.—On Oct. 11, at Eastbourne, Murtaugh Ja Houghton, M.R.C.S.

Hughesdon.—On Oct. 17, Mary Redfern Hughesdon, M.B. Ca D.C.H.

MacGillivray.—On Oct. 15, at Crail, Fifeshire, Angus MacGilli M.D. Aberd., D.SC., LL.D. St. And., F.R.S.E., 28th chief of the C MacGillivray.

Maclean.—On Oct. 17, in London, Charles Forbes Macle M.B. Glasg.

Smith.—On Oct. 13, at Woking, Surrey, Gilbert Johnston Sm M.B. Glasg., major, I.M.S. (retd.), aged 49.

Starling.—On Oct. 18, Edwin Alfred Starling, M.B. R.U.I., aged 9

Stevenson.—On Oct. 16, in Malta, Alec King Stevenson, M.B. B surgeon commander, R.N.

Notes and News

N ASSOCIATION OF MEDICAL LIBRARIANS

E inaugural meeting of a new medical subsection of the ry Association, held in London on Oct. 4, was attended brarians from medical institutions in all parts of the try. In a preliminary statement Mr. W. R. Le Fanu, rian of the Royal College of Surgeons of England, ined that a small group of medical librarians had been ng informal meetings in London during the last few and that the time had come to organise a regular group r the ægis of the Library Association. Medical librarians ndon and in the provinces had responded with enthu-, and the university and research section of the Library iation had given its official blessing to the new subsection, was now in being. Mr. Le Fanu recalled that Sir William suggested the formation of such a body as long ago as at the annual meeting of the British Medical Association, here were few regularly trained librarians at that date othing came of the proposal. Since then medical libraries expanded enormously both in size and in the services they provide, and their importance to the profession ardly be exaggerated. An association devoted to the sional interests of medical libraries deserves a warm me and strong support from all medical men.

nous projects which will advance the usefulness and ncy of medical libraries were outlined to the meeting. include the establishment of an exchange system for cate or unwanted books and journals, the compilation tion lists of periodicals and of rare books, and inter-y loans. Membership of the group is confined to members e Library Association who are working in medical es, but medical men will always be welcomed as guests; ecretary of the group will gladly answer inquiries both members of the medical profession and from librarians.

following committee was appointed to manage the of the section: C. C. Barnard, London School of ne and Tropical Medicine (chairman); Miss E. Wigmore, al Research Council; W. A. Lee, Liverpool Medical ution; W. R. Le Fanu, Royal College of Surgeons ngland; T. J. Shields, British Medical Association; ilson, Medical Library, University of Manchester; and . Bishop, Wellcome Historical Medical Museum, 28, nan Square, London, W. 1 (hon. secretary).

WHALING TODAY

a meeting of the Universities Federation for Animal are in London on Oct. 17, Dr. H. R. Lillie emphasised ruelty of the present method of killing whales by means rpoons fitted with explosive heads filled with black ler. Sometimes, he said, as many as nine harpoons sed to kill one whale, and often death does not follow ne to five hours. Among the alternative methods of g, he thought electrocution the most hopeful line to e, though possibly the use of carbon-dioxide cylinders ome merit. He mentioned that, owing to damage to the tines, whales are often rotten by the time they are ght up to the factory ship.

. John Grierson discussed the use of aircraft in whaling, confirmed Dr. Lillie's views on the brutality of present ods. Sir Robert Robinson, P.R.S., discussed other natives, including high explosive, which he no longer red, and high-velocity solid missiles

Robert Case discussed the use of carbon dioxide, and sed the importance of keeping in mind the growing use of meat for consumption when considering new methods aughter. He was afraid, for example, that the high-ure peak from high explosive might cause much damage uts containing gas, even if the missile did not in fact e the abdominal viscera. He suggested that the Depart- of Scientific and Industrial Research would perhaps leased to coöperate with Dr. Lillie in any proposed rimental work.

. Case drew attention to an industrial hazard of whaling he had studied during the past season. A very high ence of sepsis was noted amongst deck workers, and one as lost from fulminating gas-gangrene. A study of some he wounds showed a bacterial flora in which clostridia ominated, and in certain cultures brought back *Cl. naliens* had been found. The source of infection was the of rotten whales, infected from the intestinal tract ng the post-mortem interval, when the temperature aintained at about 35°C by the insulating action of the blubber. Dr. Case suggested that steps might be taken to lower the incidence of infection, and mentioned that he had already arranged for one fleet to try out prophylactic and therapeutic sera, as well as antibiotics, during the forthcoming season.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION

The scientific and technical entries for the Royal Photographic Society's Exhibition have now become so numerous as to cover the entire wall-space of the society's gallery, so the exhibition has to be held in two parts. The scientific section this year contains some entries of medical interest, with a specially strong group from the photographic department of the Westminster Hospital. Their serial comparative records of a case of arteriovenous aneurysm in the skull (600) is a model of accurate comparison photography in which the large scale and high definition, combined with the wide area of field recorded, provide an excellent visual impression of the patient's progress. This series would have been improved by lateral views to show presence or absence of proptosis. The more complete series of routine plastic surgery records (601, 602), by Alfred Benjamin, are lacking in precision. "A Pallid Kidney" (604), also from the Westminster Hospital, shows the value of including a grey-scale[1]; it would have been still better if the original grey-scale could have been attached to the mount. "Benign Pigmented Melanoma" (611), by Miss D. V. Marshall, is a good record marred by absence of any hint of the scale of reproduction of what can be guessed to be a juvenile thigh. The examples of photomicrography are mainly notable for the absence of the splendid work of J. S. Pittock.

The colour section contains fine medical prints by Edward Brain, and in the transparency cabinet Miss D. V. Marshall makes a brave attempt to present the general appearance of hæmochromatosis (343) and polycythæmia (344). In the latter she wisely included a normal control, but unfortunately chose a sallow mediterranean type which was not truly comparable; a colour-scale would have provided a more useful control.

All in all, the medical entry was disappointingly small, and many of our best workers were not represented at all. The newly established hospital photographic departments may be feeling too shy to submit entries; next year should see a much larger turnout.

This exhibition is open free to all, at 16, Princes Gate, S.W.7, until Nov. 1.

COÖRDINATION OF ABSTRACTING SERVICES

A conference of representatives of abstracting services in the medical and related sciences, held in Paris under the auspices of Unesco, agreed on the desirability of providing on a coöperative basis a scientific medical information service by means of abstracting current publications at the lowest possible cost to the reader. It was recommended that, to avoid duplication, *Excerpta Medica* and *Biological Abstracts* be asked to consider reducing the range of subjects covered by their services; and that *Biological Abstracts* and *British Abstracts* on the one hand, and *Excerpta Medica* and *World Abstracts* on the other be asked to explore the possibility of coöperation by the exchange of abstracts. The meeting recommended that, to implement the decisions taken, Unesco should set up an interim coördinating committee, composed of non-profit-making international abstracting services. Initially, the committee should be composed of the abstracting services represented at the conference (*Excerpta Medica* being invited as an observer only, until it becomes non-profit-making), the Interim Commission of the World Health Organisation, Unesco (as secretariat and convener), the International Federation for Documentation, the International Federation of Library Associations, and the Medical Libraries Association. It is proposed that the first meeting of the committee shall be held next spring.

University of London

On Thursday, Nov. 6, at 5 P.M., at 1, Wimpole Street, W.1, Mr. E. D. D. Davis will deliver the Semon lecture on the Applied Anatomy and Physiology of the Pharynx and Œsophagus. Admission to the lecture is free, without ticket.

University College, London

The remaining lectures of Dr. M. H. Pirenne's course on the Physiological Mechanisms of Vision will be given on Oct. 29 and Nov. 5 and 12, at 5.30 P.M. (and not at 5 P.M.).

---

[1] Stanford, B. *Lancet*, 1946, ii, 299.

University of Leeds

The title of emeritus professor has been conferred on *Dr. J. Johnstone Jervis*, who has lately retired from the chair of public health. The following appointments have recently been made: Dr. W. J. Allen, lecturer in physiology; Dr. I. G. Davies, professor of public health; Dr. C. W. Dixon, lecturer and chief assistant in public health; Dr. R. P. Harbord, reader in anæsthetics; Dr. R. Orton, senior lecturer in psychiatry; Mr. Harold Petty, research fellow in the surgery of rheumatism; *Dr. C. J. Polson*, professor of forensic medicine; Dr. D. E. Price, lecturer in forensic medicine.

Dr. Davies is at present deputy M.O.H. for Bristol and deputy director of the preventive medicine laboratory of the University of Bristol where he is also lecturer in public health. He qualified in 1923, and took his M.B. Lond. the following year and the M.R.C.P. in 1926. After holding resident posts at the North Wales Sanatorium and St. Peter's Hospital, London, he became tuberculosis officer and senior assistant medical officer for Nottingham. He has published papers on the Foster Child, and the 1940 and 1941 outbreaks of paratyphoid B in Bristol. In 1944 he took his M.D. Dr. Davies is a member of the Population Investigation Commission.

Dr. Polson, who is a barrister-at-law of the Inner Temple, graduated M.B. with first-class honours in pathology at the University of Birmingham in 1924. He held a lectureship in pathology at the University of Leeds before he was appointed pathologist to the Crichton Royal at Dumfries. Later he became assistant lecturer in chemical pathology and demonstrator in pathology at the University of Manchester before he returned to Leeds to take up his present appointments as senior lecturer in pathology in the university and pathologist to St. James's Hospital. His published work includes papers on liver necrosis and rhinoliths. In 1941 he was elected F.R.C.P.

University of Sheffield

Dr. J. L. Edwards and Dr. L. C. D. Hermitte have been appointed honorary lecturers in pathology, and Dr. R. T. Gaunt, honorary lecturer in medicine to dental students. Dr. H. J. Whiteley has been appointed assistant lecturer in pathology.

Royal College of Physicians of London

Dr. E. R. Boland will deliver the Croonian lectures at the college, Pall Mall East, S.W.1, on Tuesday and Thursday, Nov. 18 and 20, at 5 P.M. His subject is to be the Administration of Medicine.

Royal College of Surgeons in Ireland

The following have received the fellowship:

Denis Boland, D. M. Brooks, John Bunting, F. H. Counihan, R. A. E. Magee, Eoin O'Malley, W. J. O'Regan, A. B. Walsh.

Care of Old People

The Bristol Council of Social Service and the Bristol and District Divisional Hospitals Council are holding a conference on this subject at 2.30 P.M. on Wednesday, Oct. 29, at the University of Bristol. Dr. E. L. Sturdee and Dr. Marjory Warren will speak on the medical needs of old people, Miss D. Ramsey on their social needs, and Dr. R. H. Parry will sum up the discussion. Further particulars may be had from the hon. secretary of the Hospitals Council, Royal London House, Bristol, 1.

Course on the Rheumatic Diseases

On Saturday, Oct. 25, at 9.45 A.M., Lord Moran will open this course at the rheumatism unit of St. Stephen's Hospital, Fulham Road, London, S.W.10. On that day the following lectures will be given: Sir Adolphe Abrahams (General Physician's Approach to Rheumatic Diseases); Dr. Philip Ellman (Ætiology of Chronic Rheumatism); Dr. Francis Bach (Rheumatic Fever, and Organisation of a Rheumatism Unit); Dr. G. D. Kersley (Gout); Dr. Grace Batten (Radiological Diagnosis of Arthritis). Particulars of the lectures to be given on the second and concluding day of the course will be found in the Diary of the Week on this page.

Notices in the Newspapers

The Medical Registration Council of Eire announce that their attention has been drawn to the increasing number of notices appearing in the public press that might be construed as advertising on the part of members of the medical profession. "As notices in the public press should do no more than notify the patients of absence from or return home, or of change of address, it is the opinion of the council that: (1) no notice should appear more than once; (2) no title except that of Doctor (Dr.), or Mister (Mr.), or Surgeon should be used; (3) no degree or qualification should be inserted after the name; (4) in no case should hours or days of attendance be specified; (5) the telephone number and full address should be quoted only in case of taking up residence or change of residence."

Appointments

BUCKLEY, WILLIAM, M.A., M.B. Camb., F.R.C.S.: asst. surgeon, Nottinghamshire county council and city council.

CURRIE, DONALD, M.A., M.B. Camb.: M.O., Tanganyika, Service.

JOHNSON, H. D., M.B. Camb., F.R.C.S.: asst. surgeon, Hospital, London.

MACKAY, D. H., M.B. Manc., F.R.C.S.: surgeon, Stockport

Diary of the Week

OCT. 26 TO NOV. 1

Sunday, 26th

ST. STEPHEN'S HOSPITAL, Fulham Road, S.W.10

10 A.M. (Rheumatism unit.) Dr. Philip Ellman: Differential Diagnosis; Drug Treatment in the Diseases.

NOON. Sir Thomas Fairbank: Development of Arthritis.

2 P.M. Mr. Timbrell Fisher: Orthopædic Aspects of Disease.

3.30 P.M. Dr. Blake Pritchard: Pains—Neuritic and

4.30 P.M. Dr. David Shaw: Psychiatric Factors in the Rheumatic Diseases.

Monday, 27th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2

5 P.M. Mr. H. F. Lunn: Applied Anatomy of Testi Descent. (Arnott demonstration.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1

5.30 P.M. *Odontology.* Prof. H. F. Humphreys: Education. (Presidential address.)

SOCIETY OF APOTHECARIES OF LONDON, Black Friars Lane,

5 P.M. Prof. D. F. Cappell: Pathology of the Rhesus F

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1

8.30 P.M. Dr. A. H. Douthwaite, Mr. Norman Tanner: ment of Peptic Ulcer.

Tuesday, 28th

ROYAL COLLEGE OF SURGEONS

5 P.M. Mr. Lunn: Cerebral Cortex and the Status *(Arnott demonstration.)*

ROYAL SOCIETY OF MEDICINE

8 P.M. *Medicine.* Prof. Alexander Haddow, Dr. Eric Dr. Edith Paterson, Dr. Joan Watkinson, Dr. Warwick, Mr. E. W. Riches: Chemotherapy in Diseases.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, W.C.2

5 P.M. Dr. I. Muende: Pathological demonstrations.

INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, *Gray's Inn* W.C.1

4.30 P.M. Mr. Terence Cawthorne: Surgical Treatme Deafness.

PADDINGTON MEDICAL SOCIETY

9 P.M. (St. Mary's *Hospital*, W.2.) Mr. A. Dickson W Coloured film on Treatment of Varicose Conditions their Complications.

EDINBURGH POST-GRADUATE BOARD FOR MEDICINE

5 P.M. (Royal Infirmary.) Mr. J. M. Graham: Obstru Dyspnœa.

Wednesday, 29th

ROYAL COLLEGE OF SURGEONS

5 P.M. Mr. W. R. Douglas: Surgical Treatment of Meta Carcinoma of the Cervical Glands. (Moynihan lectu

Thursday, 30th

ROYAL COLLEGE OF SURGEONS

5 P.M. Dr. James Craigie, F.R.S.: Viruses, Self-reprod *Substances, and Tumours.* (Imperial Cancer Re Fund lecture.)

SOCIETY OF APOTHECARIES

5 P.M. Sir Lionel Whitby: Theory and Practice of Ch therapy.

INSTITUTE OF DERMATOLOGY

5 P.M. Dr. H. MacCormac: Occupational Dermatitis.

MEDICO-LEGAL SOCIETY

8.15 P.M. (26, Portland Place, W.1.) Judge W. G. Earen K.C.: Retrospect and Prospect. (Presidential addr

SOCIALIST MEDICAL ASSOCIATION

7 P.M. (Denison House, Vauxhall Bridge Road, S.W.1.) J. Ll. Saunders, B.D.S.: New Zealand National Service.

HONYMAN *GILLESPIE LECTURE*

4.30 P.M. (Edinburgh Royal Infirmary.) Dr. W. Ritchie Ru Traumatic Amnesia.

Friday, 31st

LONDON CHEST HOSPITAL, Victoria Park, E.2

5 P.M. Dr. N. Lloyd Rusby: Diagnosis of Pulmonary *culosis.*

BIOCHEMICAL SOCIETY

2.15 P.M. (St. Thomas's Hospital medical school, London, S Short papers and demonstrations.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY

8.30 P.M. Sir Archibald McIndoe: Surgery of the Burnt Hand.

ROYAL MEDICAL SOCIETY, 7, Melbourne *Place, Edinburgh*

8 P.M. Prof. W. E. Le Gros Clark, F.R.S.: Rôle of the Anat in the Study of Sensory Functions.

E PAROXYSMAL TACHYCARDIAS *

MAURICE CAMPBELL
O.B.E., D.M. Oxfd, F.R.C.P.
PHYSICIAN TO GUY'S HOSPITAL

paroxysmal tachycardias include four varieties
xysmal arrhythmia: supraventricular (auricular
dal) tachycardia (60%), auricular fibrillation
auricular flutter (6%), and ventricular tachy-
(4%). Clinically, when no electrocardiogram is
e, the diagnosis of paroxysmal tachycardia must
e to be made and will include some cases of
mal flutter with regular 2 : 1 block and some of
lar tachycardia. This will not detract from its
much as it may seem to, for they will be few and,
main, types that behave clinically like auricular
rdia.

nately the frequency and seriousness of these
mias are in reverse order, ventricular tachycardia
he least common and much the most serious.
make no distinction between auricular and
achycardia, and little if any difference has been
which is helpful, since they can only be
ished cardiographically. The two are combined
raventricular tachycardia. I may sometimes,
ers have done, use auricular tachycardia as
nous with this; in fact it may be more accurate
o, both rhythms arising in the auricular muscle,
rer to the S-A and the other nearer to the A-V

ost cases the meaning of "paroxysmal" can be
loubt; but, especially since the introduction of
e, it may not be easy to know if a rhythm was
mal or had become established. I suggest that
thm persisting more than fourteen days should
d paroxysmal without some qualification, such
racted; and that, where an abnormal rhythm
once or twice only during some other illness
iac infarction, it should be called transient rather
roxysmal. I have emphasised this with paroxysmal
ion, but it is of more general application.

uld be tedious to describe in detail how I reached
ercentage figures for the different arrhythmias.
00 patients attending the cardiographic depart-
Guy's Hospital, during 1927–36, and two years'
ents at the National Heart Hospital, have been
d. I have also modified them by the types seen
private practice and such published statistics as
ertinent, especially many papers of White, who
that, in his experience also, paroxysmal tachy-
s twice as common as paroxysmal fibrillation.

wing classical precedent I have divided the clinical
into diagnosis, ætiology, symptoms, prognosis,
atment. In some ways it would have been simpler
uss all the arrhythmias together, but this would
iven a less complete picture of any one of them.
compromised by combining all diagnosis and
ent in two sections, before and after discussing the
spects of each separately. All these arrhythmias,
utter and ventricular tachycardia, may be physio-
and of no significance in indicating heart disease.

Diagnosis

n the attack is not seen and there is only the
; reliance must then be placed on the abrupt
and the rapid beating of the heart is nearly always
st symptom felt,—whatever others may follow.
atient complaining of palpitation should be asked,
does it start? When was the last attack? How
id it last?" A decisive answer to these three questions will generally establish the diagnosis with certainty, for ordinary palpitation is much too vague and indefinite to allow the patient to define the number and length of attacks with precision. The end of the attack is as sudden as the onset, but the patient may be less capable of detecting it, as simple tachycardia may follow the paroxysm. Most other symptoms are too variable to be reliable, and extrasystoles before or after the attack may obscure the clear picture.

Inquiry must then be made about whether the heart was regular or irregular, and, perhaps surprisingly, the patient's statement usually proves to be reliable, and I have seen few instances where a subsequent record showed it to be wrong.

If the rhythm is irregular, fibrillation and flutter with varying A-V block can only be distinguished by graphic methods, unless the irregular rhythm is interrupted by regular periods, or the signs of regular auricular activity can be seen on radioscopy or in the jugular pulse. If some paroxysms are regular and some irregular, the regular are more likely to be flutter.

If the rhythm is regular, it is impossible, without graphic methods, to distinguish between auricular and ventricular tachycardia and flutter with 2 : 1 A-V block. If the patient is already under treatment, especially with digitalis, after congestive failure or cardiac infarction, ventricular tachycardia is likely, though not certain; otherwise it is unlikely because of its rarity. The help given by the rate is discussed below.

Apart from the rate, the following points may help to distinguish between paroxysmal flutter and tachycardia. If the regular rhythm is interrupted by a slower or irregular rhythm, if the rate can be halved by pressure on the carotid sinus, or if, in the longer attacks, the rate can be halved or made irregular with digitalis, the attack is flutter. Auricular tachycardia rarely lasts more than ten and generally not more than four days; therefore the longer an attack of unknown origin lasts, the more likely it is to be flutter. If the patient has heart disease, or if congestive failure develops rapidly, flutter must be thought of but cannot be diagnosed merely on these grounds. Occasionally, even when a cardiogram is obtained, there may still be difficulties—e.g., slow flutter without heart-block; and a faster rate with 2 : 1 heart-block where the P and T waves cannot be clearly distinguished. Every effort should be made to obtain a cardiogram of an attack, to make certain of the diagnosis of flutter or ventricular tachycardia—the latter being of special importance for prognosis.

Paroxysmal Supraventricular Tachycardia

My conclusions are based largely on a series of 165 cases with 66 cardiograms followed up some years. Though so many papers have been written on the subject, most deal with points of interest in single cases, and few with large consecutive series. Hume (1930) gave a valuable summary, and Cooke and White (1942) have written a useful paper on prognosis. The condition is relatively common, though those doctors who rarely diagnose it unless they see a patient in an attack will continue to think it rare, because short attacks are so much more common.

ÆTIOLOGY

The first question to decide in each patient is whether there is any organic heart disease, as this knowledge is essential for prognosis. The ætiology of my 165 cases is shown in table I, and more than half had no heart disease. There is such close agreement on this subject between these series of cases that it may be generally accepted, the percentages without heart disease being 62 (Campbell and Elliott 1939), 62·5 (Hume 1930), and 62 (Gallavardin and Froment 1930), such exact correspondence being due to chance. White also has found the majority

---

* umleian lecture delivered at the Royal College of Physicians
April 16 and 18, 1946.

without heart disease; and, if this is true of those seen by cardiologists, it must be even more true of others. If a patient has paroxysmal tachycardia, it is statistically more likely that his heart is otherwise healthy than that it is diseased.

SEX AND AGE INCIDENCE

There is no difference in sex incidence, the extra women in the rheumatic group being balanced by more men in the myocardial group. In four combined series there were 250 men and 252 women.

The age at which the attacks started is shown in table I. Briefly, 67% started before the age of 40 and only 33% after that age. With paroxysmal fibrillation the figures are almost exactly reversed, 25% before 40 and 75% after that age.

Even when there is heart disease, the onset of this is rarely the immediate cause of the paroxysms. Sudden or unexpected movements are the most common known cause, but in an even larger number of attacks there is no obvious reason for their start. The influence of various factors—infection, anxiety, indigestion, smoking, exercise, and pregnancy—in making the patient more liable to have attacks was discussed by Campbell and Elliott (1939).

SYMPTOMS OF PAROXYSMS

Apart from palpitation there may be various symptoms, any of which may be more or less prominent and exceptionally may mask the nature of the paroxysm, especially in children. Rarely, the patient may be unaware that he is experiencing an attack. The general symptoms—palpitation, breathlessness, inability to stand, faintness, dizziness, and anxiety—are of little special significance. Any degree of incapacity up to complete prostration may be met with, and may be attributed to any of these sensations; this depends mainly on the state of the heart muscle, on the length and, to a less extent, the rate of the attack, and on the mentality of the patient.

If the heart is healthy, the symptoms are generally discomfort rather than real disability. Many patients could carry on their routine work, though they found it more of an effort. At the other extreme some developed congestive failure. Many of those with rheumatic or other heart disease had little more disability than had most of the normals, yet with severe heart disease any attack may be very grave. If an attack lasts one or two days the symptoms and disability generally become important, even if the heart is healthy; but a healthy heart will support short attacks, even at such a rapid rate as 200, surprisingly well.

Loss of Consciousness.—Unconsciousness during an attack is uncommon, and equally so with paroxysmal fibrillation. It is more common with paroxysmal flutter and is generally due to the assumption of 1 : 1 rhythm, often as the result of exercise.

Anginal Pain.—Besides discomfort or tightness in the chest, present in most attacks and of no special significance, an eighth of the patients, including many with normal hearts, had more severe anginal pain during attacks, some occasionally, and others when the attack had lasted some hours. In few was the pain really severe. Anginal pain is rather less common in paroxysmal fibrillation but more common in paroxysmal flutter (a quarter of the cases). Pain, even of a severe anginal type, does not indicate an unfavourable prognosis; this must be judged mainly by the condition of the heart during the free periods.

Congestive Failure.—The occurrence of congestive failure in a paroxysm does not prove that the patient has heart disease, though if it develops soon after the start of the paroxysm it is significant. Failure, generally right-sided, was seen during one or more attacks in an eighth of the patients.

One man without heart disease, after several failure, had developed it by the eighth day of a te when the blood-pressure had fallen from 140 to 105

Another normal adult had failure in her two lon of seventeen and twenty-nine days.

Two children with normal hearts developed failure lasting two or three days, but the rates were

Most others had heart disease. One of the pietic patients is alive and in fair health *fourte* after the paroxysm, in which severe failure was the seventh day of a twelve-day attack. In *failure became apparent about the third day*, *many attacks lasting three days were observed in as they were less likely* to seek medical advice, figures quoted indicate that the development of failure depends, as a rule, on heart disease. Its does not seem so serious as might be expected, where the heart is normal or well *free intervals.*

In paroxysmal fibrillation, and *still* more in failure develops more readily, unless the rate is controlled with digitalis.

Nausea, vomiting, flatulence, and abdominal important symptoms in about a tenth of the ca longer attacks the congestion of the liver and as the result of failure may be misinterpreted and to be the cause of the attack.

Embolism.—This is a rare complication, though cerebral and pulmonary embolism have been seen. more common where there is mitral stenosis.

HEART-RATE IN PAROXYSMS

Lewis (1920) places the usual rate between 200 per min., with a range 110–220. This upper high enough; it is not very rare for it to reach 240. cases the rate was 160–200 in about half, and in 90%. In 5 cases rates were less than 140— 126, 124, and 112—and in 4 as fast as 230, 234, 240,

Table II shows how the rates were distributed all the different types of paroxysms. There were grams of 99 attacks from 81 patients (two from the patient being counted when the rate was and of 42 others observed clinically. There is no to think that the "clinical" rates are not accu except that there were fewer under 160, perhaps bec paroxysms at a slow rate are less likely to be diag without a graphic record. The rate should alway taken for half a minute. Generally, when the rate is to be uncountable, it is because an attempt has made to count the pulse by the finger instead of heart by the ear.

The range of rates does not in the main vary with type of paroxysm or on the presence or absence of

smal flutter ..	29	24	35	12	0	0	0	17

patients the auricular rate varied between 180 and minute—most commonly between 240 and 340. sual finding was 2 : 1 block; hence the ventricular was generally between 120 and 170.

table II the ventricular rates in paroxysmal tachy- and flutter are contrasted and the differences triking, though there is much overlapping. In r nine-tenths are below 180. In paroxysmal tachy- a nine-tenths are between 140 and 220. Expressed other way, if the ventricular rate is below 140, r is more likely (2 to 1); if between 140 and 180, ysmal tachycardia is more likely, but paroxysmal r is not uncommon ($3^{1}/_{2}$ to 1); but, if the ventricular is over 180, paroxysmal tachycardia is almost certain o 1). The rate of 160 is the nearest possible approach dividing line, but it is very inexact. In 52% of ases of flutter the rate is below 160; in 72% of the of paroxysmal tachycardia the rate is above 160, in nearly half 160–200.

LENGTH OF ATTACKS

aroxysms last hours much more commonly than . Though variable, they tend to have a more or customary length in any one person, who can generally rt that the attacks last between, say, two and eight rs, or less than half an hour, or more than a day, is surprised if his past experience does not prove seful guide to what to expect. The usual lengths aroxysms was up to half an hour in a third; under hours in more than half; and under six hours in three-quarters: only a tenth habitually had attacks lasting a day or more, though longer attacks are more likely to come under observation.

† Combined figures for Campbell and Elliott (1939), Hume (1930), and Gallavardin and Froment (1930).

‡ Orgain et al. (1936).

The longer paroxysms are more important, for the disability and the chance of congestive failure are increased. Of 100 patients 29 sometimes had an attack that lasted more than a day, but in 10 it was not much longer than this. Of the remaining 19 with long attacks there were 6 (including 2 children) with healthy hearts. The long attacks were least common in those without heart disease—11% of the normal, 21% of the rheumatic, and 33% of the other groups having these long attacks. All the types of attacks were represented, but there was a higher proportion of ventricular paroxysms than of the other types, nearly half the former lasting more than a day.

Even among these longer attacks relatively few lasted more than two or three days, and they were of this length in 8 of 100 patients. In 2 others they lasted four days; in 2 up to seven days; and in 5 ten days; only in 2 did they last longer than ten days. In one of these patients attacks lasted seventeen and twenty-eight days; in the other, who had had attacks for twenty years and during five years' observation had about ten a year lasting never more than forty-eight hours, three attacks lasted seventeen, twenty-nine, and about thirty-five days.

These long attacks are very unusual and more serious but they may occur without there being any disease of the heart. Most paroxysms last hours rather than days, but 30% of our patients had one or more attacks lasting a day; 10% of these very rarely, 10% occasionally, and 10% habitually. The general agreement about the short attacks is shown in table III. If the figures are combined only 20% had an attack lasting more than a day, and only 5% more than ten days.

Attacks lasting more than a month are extremely rare, but some unusual cases have been recorded where they have lasted, possibly with interruptions, up to a year. Nothing, however, corresponding to established tachycardia has been described, though the case of Miller and Perelman (1945) is of interest in this connexion.

PROGNOSIS

The immediate outlook is excellent; and, however long a paroxysm has lasted, whatever the rate, and however ill the patient may seem, he may be expected to recover. It is often stated that a patient may die in a paroxysm; this is rare, and it creates just the impression which it is necessary to avoid in the large majority, where there is no danger. Only 6 of my 166 patients have died suddenly or unexpectedly, and they will be described to justify my general optimism.

The first patient had been subject to paroxysms twenty-six years before he died, probably from a double injection of morphine from two doctors independently.

The second patient had mitral stenosis, and, after ten years of paroxysms, was admitted with pregnancy, severe anæmia, and early failure on the fourth day of an attack; she died on the seventeenth day after losing much blood with a miscarriage.

The third and fourth patients had anæmia, and one of them pelvic suppuration also; frequent paroxysms contributed to the fatal issue by pulmonary embolism from venous thrombosis. In these cases the paroxysms were not the cause of death, but they illustrate the danger of embolism and thrombosis, especially in the presence of anæmia.

The fifth patient had pericarditis and died on the eighth day of an attack.

The sixth patient has been fully reported (Campbell and Elliott 1939); after twenty-one years with attacks he died of congestive failure in a five-week attack.

Cooke and White (1942) report 7 deaths among more than 700 patients: 2 from cerebral embolism, 1 from pulmonary œdema (with mitral stenosis), 3 after operations with a great fall of blood-pressure, and 1 child with pneumonia.

These 13 cases give a good general picture of the risks: of thrombosis and embolism, especially in the presence of anæmia; of long attacks after major operations or with concurrent illnesses; of attacks precipitating failure in a heart that has little margin; and of an exceptionally long attack that cannot be stopped. If it is known that the paroxysms are not ventricular, these are, I think, the only risks.

Perhaps it is surprising that these risks are not greater. The rapid rate is a great strain on the circulation and cannot be reduced as it can in fibrillation with digoxin. The fall of blood-pressure will give some idea of the risk in a long attack and indicate when the most heroic measures should be taken to arrest it. Barcroft et al. (1921–22) found that in a healthy man paroxysms at a rate of 200 reduced the output of the heart from 78 to 13 ml. per beat, and the minute volume to less than half (from 5·5 to 2·6 litres). It is therefore not surprising that the circulation should be so much affected, and that thrombosis may develop, especially if other factors, such as anæmia and infection, predispose to it. Many extremely low pulse pressures have been found in attacks, especially with congestive failure.

If the patient is seen for the first time during a paroxysm, it is most important to decide whether there is heart disease or not. During a paroxysm murmurs may be missed and the size of the heart may be difficult to estimate, and for some days after a paroxysm the cardiogram may be deceptive. Campbell (1942) described 5 cases with striking but transient changes in the T waves suggesting cardiac infarction after the paroxysm; 3 of the patients are still alive and are thought to have normal hearts, one of them having been watched with paroxysms for twenty years. Reversible chemical changes in the myocardium as the result of a long attack are probably responsible. Others have confirmed this finding.

Having recovered, the patient will want to know the chance of another attack. Single paroxysms are rarer than with fibrillation, but one student had an attack (recorded), and twenty years have passed without a recurrence. This is, however, unusual, and paroxysms will probably recur; but, if they are frequent enough to be troublesome, steps can generally be taken to reduce their frequency.

The immediate outlook is therefore excellent in nearly all cases. Even when a paroxysm occurs after cardiac infarction, as it does in 3% (Master et al. 1937), it does not add greatly to the seriousness of the prognosis.

Ultimate Prognosis.—This depends mainly on the condition of the heart in the free intervals. The early papers were pessimistic about the outlook, but more recently there is wider agreement that the prognosis is good. Of my 92 patients seen in 1925–32 and followed up to 1938, more than half had, when they were last seen, had their attacks for more than ten years; hence there was ample opportunity to observe any changes.

Attacks may continue throughout the greater life without the development of heart disease. C (1930) cases 32 had an average duration of and 1 had a normal heart after fifty-two years. and White (1942) traced 57 of 80 with normal and found them in good health after an average twenty-five years after the onset of their p 1 after sixty-four years. Of my own cases (C Elliott 1939) 21 were in good health after an period, with attacks, of twenty years—1 years.

A decrease in the frequency of the attacks change in the patient's life is as likely as an Paroxysms do not cause progressive deteriorat less disease of the heart, though some are treatment and continue with the same frequen many years.

In one patient paroxysms started when he was 9 and continued through life; but until a few months death at 69, from leukæmia, he led an active life, recovered from pneumonia the year before.

Another started having paroxysms at 50; at 74, they were rather frequent, he was still in business and dyspnœa.

A third was 68 when he was first seen, and par started at 23 and recurred about every two weeks; had no complaint except of "a dulcimer constantly all the old tunes that had run through his life," a of increasing nerve deafness.

All these 3 patients had normal card spite of their age, and no signs of heart disease. among the rheumatic patients most have done as could have been expected had they been paroxysms.

Campbell and Elliott (1939) concluded prognosis was excellent unless, appearing late in was the first indication of coronary disease. Co White (1942), commenting on this, thought the good even when the paroxysms started late in life; of 128 patients with normal hearts started their pa after the age of 40. Excluding the 16 with pa after cardiac infarction, they found only 2 deaths, and concluded that, arising in later life, parox may warrant a more serious prognosis in comparat uncommon cases, but generally have no influence on ultimate outcome. With this I agree, as I have no more instances where paroxysms were the imme precursor of angina pectoris, and many paroxysm elderly patients where the subsequent course has satisfactory.

Paroxysmal Auricular Fibrillation

Auricular fibrillation often occurs in parox though the established form is more familiar. My clusions are largely based on 200 consecutive cases by Parkinson and Campbell (1930); many cases since have scarcely modified our conclusions, and the figures quoted without any statement of their so are taken from this series.

I am glad to have the opportunity of thanking Dr. J Parkinson for his help, and Dr. Paul White, of Boston, shall refer to his work so frequently.

ÆTIOLOGY

Is the occurrence of paroxysmal fibrillation evid of disease? Gossage and Hicks (1912) thought it m be caused by toxic or reflex influences on a healthy he Cowan (1928) has elaborated this with some stri cases and suggested that, when established, it is gener caused by organic disease but, when paroxysmal, m often by toxic or reflex factors. This distinction, tho of value, cannot be accepted without reserve, paroxysmal fibrillation often becomes established n occurs with structural disease, but some chemical lex stimulus most probably provokes the paroxysm, ther the heart itself is healthy or diseased. White ght that a fifth of his patients seen in consultation no organic heart disease.

he ætiological grouping of our patients is shown in e I. Syphilitic heart disease was found in 2·5% (and has been included in the tables with myo- al disease); it is therefore of as little importance aroxysmal auricular fibrillation as in auricular tachy- ia. There were two main contrasts with auricular ycardia: the percentage with normal hearts was 15 ead of 62; and with goitre 15 instead of 6 or less, most of these had thyrotoxicosis, which had not ys been the case with those with auricular tachycardia.

brile and Infective Causes.—Paroxysms have occurred r pneumonia, rheumatic fever, infective endocarditis, cæmia, tonsillitis, erysipelas, influenza, diphtheria. ntery, and osteomyelitis; and with simple and gnant pleural effusions, biliary colic, appendicitis, ro-enteritis, and, more often, cystitis and pyelitis n an enlarged prostate. But on the whole the short- s of this list shows that an acute infection is only an sional factor.

e action of digitalis in starting fibrillation is well ed, and was emphasised early by Mackenzie (1908). s more likely to provoke fibrillation where there is dy failure with normal rhythm. It is only under e conditions that it follows small or moderate doses. other drug produces fibrillation so often, though it has described after adrenaline, arsenic, aspirin, carbon oxide, and iodine in the treatment of goitre.

he influence of tobacco and alcohol (and even coffee) ficult to estimate. They are often used excessively patients with paroxysmal fibrillation and have been ned as the cause, but there are few reports of complete ef for any long period with abstinence from either prove them more than accessory factors, and we have patients in whom the attacks could be entirely or n partially attributed to these causes.

aroxysms are not uncommon after thyroidectomy, l may occur after other operations. Attacks have n induced by electric shocks, vagal pressure, deep athing, coughing, and straining at stool; but these unusual, and such events and sudden movements do have the same importance as in auricular tachycardia. A large meal or exercise just after a meal may provoke attack. It is difficult to establish the relation ween indigestion and paroxysms. Paroxysms are not ecognised feature of the organic dyspepsias. Dietary iscretions and overeating have often been blamed, d many patients are inclined to attribute their attacks such causes on scanty evidence, but the abdominal comfort caused by the attack may be mistaken for the se.

DURATION OF PAROXYSMS

In 160 of our 200 patients no attack was known to ve lasted more than two days. Up to eight hours, from to eighteen hours, or from about twenty-four to about ty-eight hours were characteristic answers. Unfor- nately this series was not recorded in the same way as roxysmal tachycardia, in which attacks lasting two ys or more occurred in 5% only, against 20% in roxysmal fibrillation. Orgain et al. (1936) gave the ual duration in their cases, and I have analysed their ures for comparison (table III). Nearly three-quarters my cases of paroxysmal tachycardia had a usual ration of less than six hours; nearly three-quarters those with paroxysmal fibrillation had a usual duration longer than this.

Attacks lasting more than two days only occurred in fifth of our patients. In 16 of the 29 where attacks sted four days or longer the absence of more than one two attacks showed that they were not of the usual recurrent type. In several of these fibrillation became established after only one or two paroxysms; in some it was an incident in the course of heart-failure; but in some there was no other evidence of heart disease. There were only 8 of our 200 where one of the typical recurrent paroxysms lasted more than four days. The longer attacks that were known exactly were nine, eleven, twelve, nineteen, twenty-one, and thirty days, and 6 others of about two or three weeks.

Finally, 5 other cases were really in a class by themselves, as fibrillation had been present for months or over a year when normal rhythm returned, in 3 cases during treatment with digitalis with great advantage. Lea (1918–20) recorded a short interval of normal rhythm after years of fibrillation. Cases of fibrillation stopped after thyroidectomy have been excluded.

CLASSIFICATION OF PAROXYSMS

The different types of paroxysms have often been noted. Heitz (1914) divided them into frequent short and infrequent long attacks (often with more severe symptoms). Fahrenkamp (1917) and Gerhardt (1915) distinguished the same groups, the former resembling paroxysmal tachycardia, and the latter having temporary fibrillation for days or weeks. Krumbhaar (1916) introduced the term "transient" for these, and added the type, noted by Vaquez (1911) and Mackenzie (1908), where fibrillation occurred for a short time in paroxysms before it became established. The word "transient" is not perfect as a description, since it might be applied to any paroxysm, but it serves to designate a group differing from the usual type. Most writers have found that the isolated attacks tend to last longer than those which recur often, and this was true in our series.

The following classification seems useful not only for paroxysmal fibrillation but also for paroxysmal flutter and, to a lesser extent, paroxysmal tachycardia:

Group I: Typical paroxysms occurring (1) often, or (2) at long intervals, comparable in many ways with paroxysmal auricular tachycardia (58%).

Group II: A short series of paroxysms occurring before fibrillation is established (12%). In many of group I also fibrillation will become established ultimately.

Group III. "Transient" fibrillation, very few paroxysms (generally only one), often of longer duration:

(1) in the course of heart-failure, often without affecting it (8%);
(2) after cardiac infarction (6%);
(3) associated with infections, &c.—e.g., pneumonia—(6%);
(4) with no apparent cause (10%).

Coronary Thrombosis in Relation to these Paroxysms.—Paroxysmal fibrillation is not often a striking feature after coronary thrombosis; but, if the cases are under observation in hospital, it can be noted more often. White and Bland (1931) found it in 13 of 200 cases, and Master et al. (1937) and the present series give about the same proportion. Two other patients, after having ordinary paroxysms of fibrillation for five and nine years, developed coronary thrombosis.

Paroxysms of fibrillation occur in 7% of cases of cardiac infarction and in 3% of cases of angina. A small proportion of patients with paroxysmal fibrillation have angina, and a few get anginal pain that is not of serious significance during these attacks.

PROGNOSIS

There may be a normal heart or congestive failure but most often some degree of heart disease of slow evolution. Quinidine often proves of great value. There is no doubt of the success of surgical treatment in all cases where there is goitre; thiouracil can be effective, but its rôle is still unsettled. In other cases the prevention of attacks is difficult, but they are not dangerous.

and the long history of many patients shows that paroxysmal fibrillation does not usually indicate the graver forms of heart disease.

During the Attack.—The outlook in an attack is excellent. It is rare for a patient to be extremely ill because of the paroxysm, and the danger to life is negligible, unless there is already a seriously damaged heart.

Will the paroxysm end spontaneously? It usually lasts less than four days; but after this period permanent fibrillation becomes more likely, and after seven and fourteen days increasingly probable.

Ultimate Prognosis.—This depends mainly on the heart, but it is also important to know how often the attacks will recur and what is the chance of fibrillation becoming established. A first attack is less likely to remain the only one if there is heart disease, and fibrillation is more likely to become established if there has been rheumatic carditis. The frequency of attacks is more variable, for there are patients with fibrillation present a large part of the time, and others with only a few attacks in several years, and yet others in excellent health after an interval of freedom of many years; even then, attacks may recur.

In general there is a tendency for these paroxysms to become more troublesome with the passage of time by a gradual increase in their frequency or more suddenly by fibrillation becoming established. But attacks may continue for long periods without any increase in frequency. One man has had four or five in each of the last ten years, and two others have had eight and four fairly evenly distributed throughout the same period. Occasionally the frequency may decrease even apart from treatment.

When there are not more than one or two attacks a month the prognosis is good, and the incidence need not increase. When the attacks are very frequent, fibrillation is likely to become established; but, even when they are so frequent and irksome that established fibrillation seems preferable, it is not always easy to bring about this change with digitalis (see below).

Liability to Established Fibrillation.—During a period of years fibrillation will become permanent in about a quarter of the cases. In our cases it became established in half of those with rheumatic hearts, but only in a tenth of those with normal hearts, and in about a quarter of the remaining groups.

(1) Where there had been the usual recurrent attacks, ætiology did not make so much difference, for fibrillation became established in about 15% of each group, except that with a normal heart the proportion was much less. The average interval since the first attack was three years in those with rheumatic hearts, and from five to eight years in the remainder.

(2) Where there had been attacks only for a short time before the permanent onset, they were few but often lasted unusually long, as though fibrillation had just failed to become established then. The average time elapsing here between the first attack and established fibrillation was a year, and in 12 cases it was less than six months.

Parkinson and Campbell (1930) concluded that *paroxysmal fibrillation was a troublesome rather than a serious complication*, and that the ultimate outlook depended mainly on the heart but also on the chance of fibrillation becoming established. Orgain et al. (1936) thought the prognosis of those with normal hearts was, with rare exceptions, excellent. Cooke and White (1942) increased their cases to 88 and traced 78 of them; they conclude that below the age of forty paroxysmal fibrillation may be considered as having no prognostic significance, but in later life may sometimes be the first sign of serious heart disease.

In general terms, one can say that the prognosis is that of the heart condition, only slightly modified by the paroxysms. It is possible that the heart is in the patient who is older at the start of the special care must be taken to be sure that they the first indication of heart disease.

Paroxysmal Auricular Flutter

Whether established or paroxysmal, flutter is common than fibrillation in the proportion of to 20. I have not found any paper dealing syst with a long series of cases of paroxysmal flutter; my conclusions must be more tentative. Many deal with auricular flutter as a whole, and in respects it is hard to disentangle conclusions the paroxysmal and established forms. A all cases of flutter are paroxysmal, and an the established cases have been paroxysmal rhythm becomes established. In about a third cases paroxysmal fibrillation alternates with flutter.

ÆTIOLOGY

The series all agree in the very small proportion have not got organic heart disease, but Parkinson Bedford (1927) found about 10% with hearts normal. Orgain et al. (1936) have described 7 paroxysmal flutter with hearts otherwise normal: of these would clinically have been diagnosed paroxysmal tachycardia, though even here attacks sixteen days and six weeks in 2 cases before they stopped with quinidine. On the other hand, and Bellet (1931) thought that none of their patients normal hearts.

When the series of Campbell (unpublished), P son and Bedford (1927), and McMillan and Bellet (are combined, the ætiological incidence is 26%, hyperpietic 15%, other myocardial 43%, toxic 6%, and normal 10%. Perhaps this the importance of thyrotoxicosis. The findings similar to those for paroxysmal fibrillation, except the general myocardial group is larger; rather odd obscure cases are more common, and alcohol is a m important factor with flutter.

Sex and Age Incidence.—There is a much higher p portion of men than with the other arrhythmias, eve ventricular tachycardia—more than 5 to 1. Of cases 88% were over 40 when the paroxysms start whereas with paroxysmal tachycardia 76% were und 40. In most series the highest incidence (60–70% has been found between 40 and 70 years—i.e., in old patients than those with auricular tachycardia.

The ætiology and the age and sex incidence are different from those of paroxysmal tachycardia that, even if the underlying mechanism of both rhythms were similar, some explanation of the different clinical pictures would be needed.

SYMPTOMS

Breathlessness, palpitation, weakness, faintness, and disinclination for effort are the main symptoms. Substernal pain is found in a quarter of the cases. Loss of consciousness occurs in a tenth, a higher proportion than in other paroxysms, generally due to the assumption of 1 : 1 rhythm and often caused by exertion. Embolism develops more often and, unless the rate is controlled with digitalis, congestive failure more quickly, probably because there are more often heart disease and a tendency to longer attacks. The same classification into three groups suggested for paroxysmal fibrillation is also useful for flutter.

DURATION OF ATTACKS

Ritchie (1914) said that attacks might last minutes, hours, days, or weeks. Longer attacks are more common than with the other paroxysms, and the change to established flutter takes place more often. Parkinson and Bedford (1927) considered it established if it ed fourteen days; McMillan and Bellet (1931) nd the duration ten days or up to six weeks. The ; that digitalis treatment was introduced so early and o often effective makes it more difficult to draw a between the paroxysmal and established forms.

PROGNOSIS

he prognosis depends on the heart disease and can n be judged by the speed with which congestive failure ows the onset of flutter. The presence or absence of rt disease has no effect on the chance of restoring mal rhythm with quinidine or digitalis but influences chances of maintaining it. Cooke and White (1942), owing up some patients with normal hearts, found n still in good health from seven to thirty-two rs later.

(To be concluded)

HE DELAYED IMMUNITY RESPONSE

MOLLIE BARR
M.Sc. Lond., A.R.I.C.

A. T. GLENNY
B.Sc. Lond., F.R.S.

rom the Wellcome Physiological Research Laboratories

HE goal to be aimed at in any scheme of prophylactic ive immunisation is the production of a permanent el of antitoxin concentration, sufficient to neutralise toxin produced in the early stages of infection, and th a degree of potential immunity that a rapid protion of antitoxin will ensue, sufficient to neutralise toxin, however severe the infection.

xperiments made by us during the past 10 years e brought to light two observations that bear on e points: first, it is possible so to immunise an mal that the production of antitoxin continues almost efinitely; and secondly, the injection of an antigen o a potentially immune animal may give rise to two pes of response in the same animal, the secondary ponse being often followed by what we may describe, want of a better term, as a delayed response. The pid rise in antitoxic value during the first 10 days ter a second injection is followed by a fall for about months, after which the antitoxic titre may steadily e again for several months.

Most of the early work by Glenny and Sudmersen[1] immunity response was carried out with toxintitoxin mixtures as the primary stimulus; little work as done with toxoid either as primary or secondary imulus, and none at all with the modern prophylactics .A.F. or A.P.T. now in general use for human immunisaon. The intervals between first and second injections ere often several months, in contrast to the 4-weekly nterval customary in human immunisation at present. Certain conclusions drawn by these workers therefore equire extending, if not revising, in the light of recent xperiments. Some of the data obtained by us may assist n the determination of the best methods of testing any new prophylactics and possibly throw some light on the requirements and conditions necessary for the satisfactory immunisation of children.

ABLE I—PERCENTAGE AMOUNT OF TETANUS ANTITOXIN REMAINING IN HYPERIMMUNISED HORSES ABOUT A YEAR AFTER THE LAST INJECTION

No. of immunisations	Percentage of antitoxin remaining	Interval since last injection (months)
41	87·9	13
13	15·4	12
6	6·0	17
5	8·3	12
3	5·5	11
2	1·4	14
1	2·3	12

We have found that many horses used in the production of therapeutic serum continue to form antitoxin a very long time after specific immunisation has ceased.

In October, 1937, horse 7665 received an injection of 10 ml. of tetanus alum-toxoid, which was repeated 4 weeks later. These injections constituted the routine prophylactic measures used for all horses as a protection against accidental infection with tetanus.

For 2 years the horse was used for the production of anti-pneumococcus serum and in November, 1939, started courses of injections of tetanus toxin, continuing until April, 1945, and yielding during these 5¹/₂ years a total of 1,190,000,000 international units of tetanus antitoxin from bleedings.

When the antitoxic titre had fallen to 1150 units per ml., tetanus immunisation was not pursued further, and the horse was used for other purposes. The last injection of tetanus toxin was given on April 13, 1945, and the antitoxic value on May 21, 1946, was 1000 units.

Thus after an interval of 13 months, during which no specific stimulation was given and 144 litres of blood was withdrawn, the antitoxic value was 87·9% of the value when injections ceased.

It is of interest to compare the rate of loss of tetanus antitoxin among horses less well immunised. Table I shows the correlation between number of immunisations and percentage of antitoxin remaining: the longer the immunisation, the more antitoxin remains; the two discrepancies in sequence in the second column are probably due to the differences in interval since the last injections (column 3).

Similar results have been obtained on a larger scale from horses hyperimmunised with diphtheria toxoid and toxin, and tested at short intervals after the cessation of injections. The average loss during the first few months was about 50% per month but was practically negligible after 6 months. Well-immunised horses contained 10–20% of the antitoxin present at the conclusion of immunisation 6, 12, or 18 months later, though they had received no further injections of diphtheria toxin and had had many 8-litre bleedings.

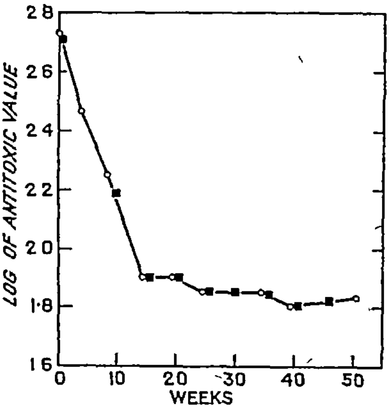

Fig. 1—Logs of diphtheria antitoxic content of a hyperimmunised horse during a year after end of the last immunisation: circles, observed antitoxic values; squares, occasions on which 24 litres of blood was withdrawn in 8 days.

Fig. 1 shows the antitoxic titre of a horse after hyperimmunisation with diphtheria toxin had ceased. About 42% of the titre was lost per month during the first 3 months of observation, reaching 15% of the original titre after 14 weeks.

After this there is an abrupt change in the shape of the curve, the antitoxic value never falling below 12% of that at the beginning of the experiment, from this time up to 50 weeks after the last injection of toxin. During this period 168 litres of blood were withdrawn from the horse.

It therefore appears that the production of antitoxin in a hyperimmunised horse may continue for at least a year after the last specific stimulus. It is of interest in this connexion to recall the findings of Glenny and Sudmersen[1] on immunising a guineapig with a single injection of a diphtheria toxin-antitoxin mixture. The antitoxic response of this animal was measured by means of tests on bleedings taken over 20 months, during which the guineapig gave birth to eight young. Despite this and the increase in weight of the animal and the fact that blood was withdrawn from time to time for titration,

TABLE II—ANTITOXIC VALUES OF GUINEAPIGS, 10 DAYS AFTER THE SECOND OF TWO INJECTIONS OF DIPHTHERIA TOXOIDS, GRADED ACCORDING TO ANTITOXIC RESPONSE

Antitoxic value	No. of guineapigs			
	Grade A	Grade B	Grade C	Grade D
Under 0·001 unit ..	0	25	38	39
0·001 to 0·01 ..	0	19	4	11
0·01 to 0·1	9	16	13	2
0·1 to 1·0	64	91	35	4
1·0 to 10	96	84	2	0
Over 10	9	13	0	0
No. of animals ..	178	248	92	56
No. of toxoids ..	15	22	8	6
Median antitoxic value (units per ml.)	1·74	0·567	0·0504	Under 0·001

the authors found that "the total antitoxin present steadily increased for at least a year after the injection."

Since this time we have followed the course of production of antitoxin in several hundred guineapigs, used to measure qualitative differences in diphtheria toxoids. The guineapigs were injected with 2 Lf doses of various batches, reinjected after 4 weeks, and bled at fixed intervals thereafter, groups of 10 to 15 animals being used for each batch of toxoid. On the basis of the antitoxic titres of bleedings 10 days after the second injection, the toxoids were graded as follows:

(A) No antitoxic values under 0·01 unit per ml.
(B) From 1 to 3 per group under 0·01 unit.
(C) At least 3 under 0·001, but some over 0·2 unit.
(D) Not more than 1 per group over 0·1, and many below 0·001 unit.

The results of grading and numbers of guineapigs are given in table II. Median values are given rather than geometric means, because some titres are under 0·001 unit.

Fig. 2 shows the antitoxic titres of guineapigs bled at definite intervals after their second injection of antigen, and the titres shown as the median values for each group. Owing to the amount of labour which would have been involved, the guineapigs were not individually labelled. Most of the animals were obtained from outside dealers, and the death-rate was therefore relatively high over the whole period of the experiment. Fig. 2 includes curves for A.P.T. in doses of 1 Lf (curve 1) and 0·1 Lf (curve 4): curves 2, 3, and 5 represent the values of guineapigs immunised with grade A, B, and C toxoids respectively. The essential details calculated from the experiment are given in table III.

The toxoid curves 2, 3, and 5 show a preliminary drop in antitoxic value of 65–69% (the equivalent of 80–82·8% per month) from 10 days to 4 weeks, but the loss during the next 4 weeks is much less, being greatest with the best toxoids (grade A) and actually becoming an increase with group-C toxoids. In curves 2–5 a considerable increase is apparent at 24 weeks over that found at the lowest point at 4, 8, or 12 weeks; the amount of this increase ranges from 58% to such result is shown in guineapigs injected wit dose of A.P.T. (curve 1), a slight but steady drop observed from the 4-week value to the conclusion experiment. It is not possible to calculate median for guineapigs injected with grade-D toxoids, too many titres are below 0·001 unit per ml.; calculated for several of these animals with values 0·001 unit, however, give a curve similar to that for grade-C toxoids (curve 5).

TABLE III—CHANGE IN ANTITOXIC VALUE OF GUINEAPIGS AFTER IMMUNISATION

Period		Calculated percentage change per month				
		Curve 1	Curve 2	Curve 3	Curve 4	Curve 5
10 days to 4 weeks	loss	65·5	82·2	82·8	38·2	80·0
4–8 weeks	loss	61·1	37·5	22·1	17·7	..
	gain	..	..	..	..	86·2
8–24 weeks	loss	26·7	..	..	..	15·8
	gain	..	66	128	28	..
Time (weeks) of lowest value ..		..	8	8	12	4
Percentage gain in value from lowest to 24 weeks		..	66	128	68	58

It is probable that the configuration of the curve poor-quality toxoids C and D is due at least in to the mixed population of responders among the pigs. Relatively high titres given by some at 10 days, as a secondary response, had fallen the intermediate response of other animals. This tion cannot, however, apply to the curves for and B toxoids; among the antitoxic values of the A at 10 days, none was below 0·01 unit and 95% 0·1 unit. Practically all these animals must have a secondary response at 10 days, and following this was a delayed response giving a second rise in value 8 weeks.

Of guineapigs injected with B toxoids, only had no detectable antitoxin and 75% had over 0·1 after 10 days. To conclude that the presence of peaks in curve 3 was due to the existence of two po tions of responders, it would be necessary to that this 75% of animals produced over 0·567 ml. in 10 days, and that 65% of this antitoxin wa in the next 18 days; little would remain after 24 The remaining 25%, more than half of which had useful titres after 10 days, would continue a slow p tion of antitoxin for 6 months, eventually values appreciably higher than those reached by good responders after 10 days. This is so imp that this explanation can be rejected.

TABLE IV—CHANGE IN ANTITOXIC VALUE OF GUIN FROM THE 8TH TO THE 12TH WEEK AFTER THE S INJECTION OF TOXOID

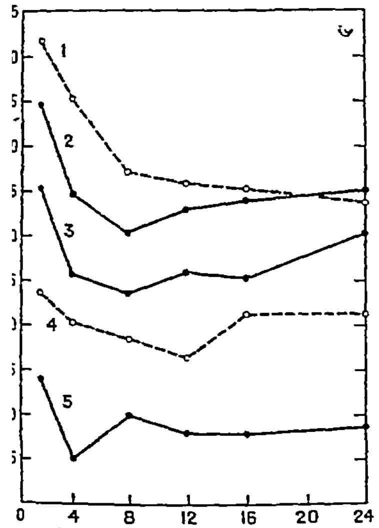
No. of guineapigs	Geometric mean of antitoxic value at 8 weeks	Percentage change value, 8th to 12th we
9	0·441	− 39·2
11	0·776	− 7·1
9	0·631	+ 0·3
5	0·0776	+ 20·3
10	0·431	+ 46·3
9	0·205	+ 64·5
11	0·340	+128·6

One experiment was made in which the titres individual guineapigs were followed: these anim received an injection of 0·25 Lf dose of A.P.T. followe 4 weeks later by 0·1 Lf dose of toxoid. Tests on bleedin were made at about twofold differences—i.e., 0·1, 0· *0·5, 1·0, &c., units—thus small differences in titre wou* not be detected. It was found, however, that sev guineapigs out of eight showed a fall in titre to a h from 10 days to 4 weeks, and one did not fall to a h until 8 weeks. Of the seven animals surviving 6 month three gave a twofold, and the remainder a greater, increa from 4 to 14 weeks. A further group of eight guineapig received the same primary stimulus but 1 Lf dose of toxoid as secondary stimulus. Of these, seven showed a fall in value between 10 days and 4 or 8 weeks, the eighth remaining constant; five showed a rise from 4 or 8 weeks to 24 weeks, and three remained constant. When the secondary stimulus was increased to 10 Lf doses, four guineapigs out of ten showed a fall followed by a rise in value; in most of the others the values remained constant, and all were over 1·0 unit per ml.

It is possible that the deaths in the animals used in experiments shown in fig. 2 may influence results and

T some conclusions unsound. Guineapigs dying possible infections might well show a lower antivalue than those surviving the full 6 months; the median antitoxic value would tend to rise. An analysis has therefore been made of groups injected with 7 batches of grade-A toxoids, in which no deaths took place among 72 guineapigs between 8 and 12 weeks. The results are given in table IV.

Further, it might be that the curves in fig. 2 represent the result of a gradual primary response from the first injection with an independent secondary response super-ed. Against this, we have tested one batch of l on four different occasions by giving guineapigs le injection of 10 Lf doses, and obtained a median of 0·00167 units per ml. 6 months later. The toxoid was tested on four occasions by injecting loses repeated after 28 days, and the median value ıed at 6 months was 0 40 units per ml., the curve htoxic titre being similar to that of curve 2. This ın value is very considerably higher though the amount of antigen used was less than that used in ngle-dose experiment.



Logs of median diphtheria antitoxic content rge groups of guineapigs bled at different s during 24 weeks after second of two tions given at an interval of 4 weeks: 1, 1 Lf P.T.; 2, 2 Lf of toxoid grade A; 3, 2 Lf of id grade B; 4, 0 1 Lf of A.P.T.; 5, 2 Lf of id grade C.

We therefore conclude that the injection of 2 Lf ses of toxoid into guineapigs, already immune as a sult of a previous similar injection, is followed by o independent responses in the same animal. In . 2, curve 1, where no rise in antitoxic value occurs ter 4 weeks, there is a rapid reduction in the rate of s, which may be due to the loss being partially mpensated by increased production after 8 weeks.

It is difficult to explain these results on the basis of imary and secondary response. It appears possible to that the two types of response (secondary and delayed) scribed here may be explained by differences in the gree of sensitisation of parts of the immunity-producing echanism of the body. On this hypothesis, some oportion of the mechanism, depending on the nature d amount of the primary stimulus, would become nsitised in such a way that a further injection would oduce a rapid rise—i.e., a secondary response—in ititoxic value. The same phenomenon would occur ter any injections given subsequently. Other tissues quiring a bigger stimulus or a longer rest from rther stimulation would not produce antitoxin rapidly it slowly and continuously, in contrast to the pical secondary rise and rapid fall. It appears from e results on tetanus horses that this capacity for ow-continued production is increased with length of munisation.

As we stated previously, in human immunisation a ate should be reached in which a child coming into contact with infection should possess sufficient circulating antitoxin to neutralise any toxin produced in the early stages and have sufficient potential immunity to bring into play a rapid production of much greater amounts of antitoxin. This would necessitate the establishment of a reasonably high antitoxic titre, maintained for several years as a result of the continued production, or delayed response, which we have described. Further, a sufficient proportion of the immunity-producing mechanism should be sensitised to the rapid type of production of antitoxin so that a secondary response, involving a very considerable rise in circulating antitoxin, would follow any infection. These considerations suggest that, when a new type of prophylactic is tested, Schick testing should be postponed until 4–6 months after the second injection in some of the test subjects.

SUMMARY

Antitoxin-production in animals continues for months or years after the injection of the last specific stimulus.

The injection of a toxin or toxoid into a potentially immune animal may give rise to two types of response in the same animal, the secondary response being followed by a delayed response in the form of a slow rise in antitoxic titre 2–3 months after injection.

There is a definite relation between the percentage of tetanus or diphtheria antitoxin remaining in the blood of hyperimmunised horses about a year after their last injection and the number of immunisations the horses have undergone. One horse, 13 months after its last injection, showed an antitoxic titre 88% of that observed when injections ceased. This animal had been under hyperimmunisation to tetanus for about $5^1/_2$ years.

SALT METABOLISM IN ACUTE PORPHYRIA

REPORT OF TWO CASES

Geoffry C. Linder
M.D. Lond., F.R.C.P.

From the Department of Pathology, University of Cape Town

Though acute porphyria is one of the rarer diseases, Waldenstrom (1937) found it fairly often in Scandinavia, and more cases are being reported elsewhere as clinicians become more aware of the disorder and of the variations in the pigments which may occur with it in the urine. Kooy (1939) and Barnes (1945) have reported cases in South Africa.

It is now recognised that "acute" porphyria is a hereditary constitutional disease which may be latent or chronic, and that crises arise spontaneously (acute idiopathic porphyria) or may be precipitated by taking certain drugs, particularly sulphonal and the barbiturates (acute toxic porphyria).

The crisis has two phases. It starts by simulating an abdominal emergency, with diffuse crampy pain extending into the groins, and severe vomiting with constipation, or else an attack of stone, with pain in the back and "hæmaturia." There is often a peculiar psychical state which resembles hysteria, and the neurological aspect may be emphasised by the occurrence of temporary paralyses or blindness. Sometimes consciousness is impaired. Radiology and laparotomies have shown segments of dilated bowel, and lesions of the cœliac plexus have been described. The second phase is characterised by the development of an ascending paralysis of the Landry type, which often extends to the bulbar centres, leading to death from respiratory paralysis. More than half the victims die in their first attack.

The first necessity is to recognise the nature of the emergency and to apply such measures as are available to remedy the abdominal symptoms. A search for porphyrin may be suggested by the colour of the urine, but porphyrin is usually accompanied by many other pigments (porphobilin, skatole red, urofuscin, indole, and tyrosine derivatives) which make the expected easy recognition of the spectral bands of porphyrin difficult. The urine may not be abnormally pigmented when fresh, and porphyrin may not be present in recognisable amounts, but porphyrin may be identified by finding porphobilinogen or a porphyrin metal complex.

Porphobilinogen (Waldenström and Vahlquist 1939).—This precursor of porphyrin appears very constantly in the urine in porphyria. It contains two pyrrol groups, whereas porphyrin contains four in a ring. With Ehrlich's aldehyde reagent it gives a red compound similar to that given by urobilinogen; these compounds have slightly different spectral bands and may be readily separated by extraction with chloroform, in which the urobilinogen compound is freely soluble, whereas the porphobilinogen compound is very insoluble in organic solvents. Porphobilinogen in urine does not give Schlesinger's reaction after oxidation; urobilinogen does. On being treated with acid, porphobilinogen forms a red pigment, porphobilin, which has a single spectral band at 500, and on further heating porphyrin can be obtained. Porphobilinogen is of great practical importance in the recognition of porphyria because of its constant presence and its easy recognition by the aldehyde reaction with chloroform extraction (Watson and Schwartz 1941).

Porphyrinogen (Waldenström 1937, Chandler et al. 1939).—This term was used for all the colourless substances which change to porphyrin on standing or heating the urine with dilute acid. Of these porphobilinogen is the most important.

Porphyrin Metal Complex.—This zinc compound gives the urine a red colour and a spectrum closely resembling those of hæmoglobin, but the supposedly blood-containing urine contains no protein or red cells and does not give the benzidine or guaiacum tests; acidification with hydrochloric acid changes the spectrum to that of acid porphyrin. This substance has probably caused considerable confusion in the separation of porphyria from hæmaturia.

When a porphyria is recognised, the risk of a fruitless laparotomy is avoided, but the problem of treatment remains acute. There is no fundamental remedy, for the basis of the disorder is uncertain. Waldenström (1937) compares the relationship of porphyrin to porphyria with that of uric acid to gout, and claims that, in both, the observed chemical changes are the signs of a more deeply seated metabolic disorder. Nesbitt (1944) has collected evidence that porphyrins may interfere with the autonomic nervous system, and Thorner (1937) records the case of a patient treated with a porphyrin compound who developed a severe peripheral neuritis. Spasm of the blood-vessels may be shown by hypertension and changes in the electrocardiogram, and Waldenstrom (1937) has observed contraction of the retinal vessels, with amaurosis.

Treatment must therefore be directed to the relief of pain, the correction of dehydration which may have followed the vomiting, and the use of glucose, insulin, vitamins, and liver extracts in the hope of doing good. Though treatment for dehydration is often applied, it does not appear to be recognised how severe is the disturbance of mineral metabolism in some cases, and that the rectification of this may be important in meeting the crisis. In the cases reported here the mineral metabolism suggested adrenal failure.

CASE-RECORDS

Case 1.—A European woman, aged 29, developed in *April, 1944*, an ulcer on her leg after an injury. It was treated with sulphanilamide powder and had almost healed in June. On *May 21* an itching vesicular eruption appeared on her hands; the vesicles burst and dried up, but the rash spread over the legs, forearms, and face. On *May 24* she had nausea and abdominal pain and began to vomit persistently. On *May 30* she had a vaginal discharge and tenderness in both fornices, and sulphadiazine was given for a possible salpingitis. After being given sulphadiazine 13 g. she developed tinnitus and deafness, swollen slight mental confusion; the drug was stopped.

On *June 3* the urine became very dark, and she convulsion, followed by coma. Examination numerous scabs on arms, legs, and face, and a few vesicles. No œdema or jaundice. Temperature 99°F, rate 100, respirations 30. Chest and abdomen normal vaginal discharge. Blood-pressure (B.P.) 110/58 equal, reacted sluggishly to light. Fundi normal. Ab reflexes absent. Tendon reflexes present. Right response flexor; left response indefinite. Urine: sp. gr. dark port-wine colour, trace of albumin, acetone porphyrin and urobilin present. Red cells 4,500,000 c.mm., Hb 94%, white cells 11,300 per c.mm. (dif count normal). Cerebrospinal fluid (C.S.F.): colour clot, protein 15 mg. per 100 ml., no globulin, chloride per 100 ml., normal sugar, no cells in 1 c.mm chemistry: serum-chloride 422 mg. NaCl per 100 content 52·4 volumes %; sodium 280 mg., 22·6 mg., urea 44 mg., and protein 6·9 g. per 100 ml. ment was begun with intravenous saline and glucose, and desoxycortone, and liver extract. Vomiting

June 4: B.P. 130/80; red cells 4,000,000 per Hb 80%, white cells 6400 per c.mm. Patient could relatives. Knee-jerks and ankle-jerks present; left response extensor. *June 5:* improvement maint serum-chloride 515 mg. NaCl per 100 ml.; van den direct negative; serum-bilirubin 0·5 mg. per 100 *June 6:* improving; intravenous saline and glucose cortin given. *June 7–11:* Condition satisfactory; consciousness; patient took food with extra salt vomiting; no cortical extract given. Pulse-rate rose 80 to 100 on 8th and 120 on 10th. *June 11:* in arms and hands; tendon reflexes brisk in arms, in legs. *June 12:* paræsthesiæ more intense; ton much diminished in arms and legs; patient felt B.P. 120/80; serum-chloride 436 mg. NaCl per 100 sodium 301 mg., potassium 18·8 mg., urea 50 mg., and 7·6 g. per 100 ml.; intravenous saline and cortin *June 13:* felt better; B.P. 140/90. *June 14:* sudden of rapid breathing, dyspnœa, and tachycardia, fol death from respiratory failure in about 20 min.

Necropsy.—No gross disease. Suprarenal glands 16 no macroscopic or microscopic abnormality. Tubes ovaries normal.

Urinary Pigments.—The urine contained a red pig which showed the spectroscopic bands of alkaline porph and a red fluorescence in ultraviolet light. Ehrlich's re gave a strongly positive reaction; this was shown to due to urobilinogen and porphobilinogen. Schlesing reaction ++. The porphyrin was adsorbed on kiesel as directed by Rimington (1943). It was insoluble in but soluble in ethyl acetate at pH 3. It was prob uroporphyrin III, but an attempt to prepare its methyl failed.

Case 2.—A European woman, aged 31, admitted to hosp on *Nov. 26, 1945*. She had had abdominal pain at interv for a year, and for five days it had been very severe. radiated from the loins into the iliac fossæ and down the She had taken many medicines, including sulphanilam without relief. For a year the urine had been dark fr time to time, and it had been thought to contain blo but this had not been proved. No action of bowels attack began; no vomiting. General condition poor; she was drowsy at times. Temperature 99°F, pu 120, respirations 24. General tenderness of abdomen local signs. Heart, lungs, and pelvic organs normal. Ref normal. Nothing abnormal noted in urine.

She became increasingly irrational, and her legs beca weak.

Nov. 30: the urine became reddish-purple, and porph was found. There was flaccid paralysis of both legs, fair strength in arms. Tendon reflexes present in absent in legs. Plantar responses flexor. Urine: trace urobilin; no sugar, acetone, albumin, or bile. Red 5,510,000 per c.mm., Hb 86%, white cells 14,200 per c.m (polymorphs 89%). C.S.F.: protein 35 mg. per 100 ml minute trace of globulin, chloride 502 mg. per 100 ml, CO 39 volumes %, sodium 310 mg. per 100 ml., 10 lymphocyt 2 polymorphs, and 1080 red cells. Blood: icteric ind less than 3; sugar 83 mg. and urea 137 mg. per 100 Urine: chloride 1·55 g. per 100 ml.

EPLETION OF SERUM-CHLORIDE IN ACUTE PORPHYRIA

Case	Serum-chloride (mg. per 100 ml.)	Serum-CO_2 (vol. %)	Blood		Remarks
			Non-protein nitrogen (mg. per 100 ml.)	Urea (mg. per 100 ml.)	
1.. ..	422	52	..	44–59	Persistent vomiting
2.. ..	562*	39*	..	137	No vomiting
(1935) .. e 1	437	..	280	..	Hypochlorä-misch Uramie
itt and ins (1942) e 4	476	..	..	54	Vomiting ++

tt (1944) e 1	382	43	..	42	

* Cerebrospinal fluid.

. 1: patient much more irrational and difficult to rouse; paralysed, and all tendon reflexes absent; respiratory ess. By noon the cranial nerves were involved and was unconscious; death took place suddenly soon after. *ecropsy* was delayed by legal formalities; no gross se was found.

ine.—Three bands of alkaline porphyrin were seen, on addition of hydrochloric acid the bands of acid porn appeared. Porphobilinogen reaction + +. Schlesinger's on feebly positive. The porphyrin was not soluble ther.

the families of neither patient was there any history esting porphyria, and the urines of accessible tions contained no porphyrin or porphobilinogen.

DISCUSSION

wo points of special interest arise in case 1—the tion of the sulphanilamide to the porphyria, and the ning of the disturbances of mineral metabolism. phanilamide was given in case 2 but was less likely have been an important factor; again there was a y abnormal mineral picture.

hat porphyrin was often found in the urine after atment with sulphonamides was discovered soon after se drugs were extensively used. It accompanied the thæmoglobinæmia and was small in amount (Rimington and Hemmings 1938, 1939). Its occurrence depended the quantity of sulphonamide taken and only to a all extent on the make-up of the patient; there re no symptoms referable to the porphyrin, which appeared from the urine when the drug was stopped. was an exaggeration of the normal excretion of roporphyrin—a porphyrinuria, not a porphyria. porphyria the abnormality is in the patient. The phyrin excreted is uroporphyrin, and in acute porphyria it usually belongs to series III. If a drug is cerned it may have a trigger effect so that a few es or even a single dose may provoke a crisis, or e after a long period of treatment with a drug a sis occurs and as a rule will recur if ever the drug is en again.

t seems probable that sulphanilamide played a part case 1. The danger of allergic sensitisation of a tient to sulphonamides by local applications has been wn by Tate and Klorfajn (1944) and by Park (1944), d it seems that the sensitivity is often to the sulphonide group and not to the side-chain—therefore the tient is sensitised to the whole group of sulphonamides. is very probable that the dermatitis was caused by sitisation to the sulphanilamide applied to the ulcer, d that the general reaction after the sulphadiazine s due to sensitisation to the group. The sequence of events may have been latent porphyria, sensitisation to sulphanilamide, generalised allergic reaction to sulphanilamide and sulphadiazine, a crisis of porphyria; but it seems probable that the abdominal pain, diagnosed as salpingitis, was the beginning of the crisis of porphyria, and that the sulphadiazine merely added insult to injury. In the recorded cases of porphyria sulphonamides are under suspicion but do not seem to have been definitely incriminated; they have usually been given after the onset of the abdominal pain, but Nesbitt and Watkins (1942) record a case in which an acute attack followed treatment of an infected tooth socket with sulphanilamide.

A gross depletion of serum-chloride has been noted in several cases of acute porphyria (see table). This hypochloræmia has not been commented on and has presumably been attributed to the vomiting, for treatment has usually been directed to the correction of dehydration. Vomiting alone causes a fall of serum-chloride but as a rule it is accompanied by an increase of bicarbonate and alkalosis. In the cases of porphyria in which the data are given there is no increase in bicarbonate, and in some of them the bicarbonate is low. The possibility of an adrenal insufficiency will therefore bear examination.

The characteristic changes in the blood in adrenal insufficiency are hæmoconcentration; an increase in blood-urea; a decrease in serum-chloride and sodium, with normal or low bicarbonate; and an increase in serum-potassium. The urine contains chloride and sodium in considerable amounts. In Addison's disease there are also low blood-pressure, vomiting, weakness, and pigmentation. Investigations were carried out in case 1 to see to what extent these features were present, and a less thorough study was possible of case 2. As judged by the red-cell count, hæmoglobin, and serum-protein, the hydration of the blood was normal in case 1, but the red-cell count was high in case 2—5,500,000 per c.mm. The blood-urea was 44 mg. per 100 ml. in case 1, which is high for a woman aged 29, and 137 in case 2. In case 1 the serum-chloride was 422 mg. per 100 ml. (normal 560 +), and in case 2 the C.S.F. chloride was 562 mg. per 100 ml. (normal 700 +); a low amount of C.S.F. chloride indicates a proportionately low serum-chloride (Linder and Carmichael 1928). In case 1 the serum-sodium was 280 mg. per 100 ml. (normal 320 +), and in case 2 the C.S.F.-sodium was 310 mg. (normal 300–340), which indicated a normal serum-sodium level. In case 1 the serum-potassium was 22·6 mg. (normal 18–20). The serum-CO_2 in case 1 was 52 volumes % (normal 55–75) and the C.S.F.-CO_2 in case 2 was 39 mg. per 100 ml. (normal 42–56). In general these findings resemble closely those found in adrenal insufficiency.

Aitken (1929) has found that in experimental depletion of body salt in normal people there is a zone between 585 and 555 mg. of NaCl per 100 ml. of serum above which chloride excretion is considerable and below which it is reduced to a trace of about 5 mg. per 100 ml. of urine; he has emphasised that this zone may be different under other conditions, and that the body has a great capacity for retaining salt offered to it when in a depleted state. With a normal power of chloride conservation the urine of cases 1 and 2 should have been practically chloride-free. The urine of case 2, far from being chloride-free, contained 1550 mg. NaCl per 100 ml. Chloride was not measured in the urine of case 1 until after cortical extract and salines had been given; the excretion then was high. After her relapse on June 12 it was found that with a serum-chloride level of 436 mg. per 100 ml. the urine contained 540 mg. per 100 ml. and 3·1 g. was excreted in the day. There was therefore in both cases a definite failure to conserve chloride.

Such a failure to conserve chloride with a low serum-chloride level is not confined to adrenal failure. It may occur occasionally in diabetic and nephritic acidosis. It is probably usual in respiratory diseases severe enough to lead to "free CO_2 excess"; the compensation for this deviation of acid-base balance is an increase of serum-bicarbonate at the expense of serum-chloride, the total base remaining unaltered. This low serum-chloride level can only be established and maintained by the excretion of chloride in the urine. It has been found in emphysema and sometimes in tuberculosis (Winkler and Crankshaw 1938, Thorn et al. 1940). With the vomiting of pyloric obstruction there is a loss of hydrochloric acid, which leads to a state of alkalosis with high serum-bicarbonate and low serum-chloride levels; in the urine there is usually little chloride and sometimes much bicarbonate, the chloride reappearing promptly when the serum-chloride level is restored (Anderson and Lyall 1937). In the present and similar cases there was no evidence of respiratory weakness when the low serum-chloride level was discovered. Vomiting did not occur in case 2. In case 1 it was a prominent feature, but the absence of alkalosis at least suggests that the hypochloræmia was not established by vomiting alone. In neither case was there diarrhœa or constant albuminuria; so a combination of vomiting with alimentary or renal acidosis is unlikely. The retention of urea was an extrarenal azotæmia, but one of the characteristics of this when not of adrenal origin is the small amount of chloride in the urine (Zondek 1940). In severe disturbances of acid-base metabolism excretion of chloride may occur in spite of depleted serum-chloride, but there was no such grave acidosis in these cases.

The result of treatment with cortical extract and salt was excellent in case 1. Before this she was comatose and vomiting continually; in a few hours consciousness began to return and vomiting ceased, and in three days she could take normal food with extra salt. The subsequent development of progressive neuritis was an independent event, but the low serum-chloride level at that time suggests that the need for cortical therapy had not passed or had returned.

Pigmentation was absent in these patients, but Muller (1894) and Roth (1935) have described cases of porphyria with pigmentation similar to that of Addison's disease, and Waldenström (1937) records pigmentation which he thought might be of adrenal origin, though he could not obtain other evidence of adrenal disorder. Campbell (1898) reported degeneration of the epithelial cells of the cortex in a case of porphyria, and Geissler (1939) found "Starker Lipoidgehalt der Rinde" in another.

The suggestion of a functional adrenal insufficiency is not altogether fanciful. Hypertrophy of the glands, and changes in the urinary excretion of 17-ketosteroids and other cortical waste products after infections, burns, and operations, give a firm basis to the assumption that in such conditions a large demand is made on the adrenals (Albright 1943, Shipley and Dorfman 1946). That in porphyria a similar demand is made is not unlikely, and it appears from the present cases that sometimes it cannot be met, and that a state of relative adrenal insufficiency ensues.*

The prognosis of acute porphyria is grave, for there is no known way of stemming the progress of the neuritis. The death-rate is very high, and of those who survive the initial attack many succumb within a year; a few however do survive for years—one for over 35 years (Waldenström 1937)—therefore any contribution to the successful treatment of the acute attack has some and it is suggested that cortical therapy and worthy of a further trial in suitable cases.

SUMMARY

The mineral metabolism of two patients with porphyria suggested a state of functional adrenal and encouraging results were obtained in one case cortical extract and salt.

In one case the porphyria followed allergic to sulphanilamide.

I wish to thank Prof. F. Forman and Dr. M. H. their help in studying these cases.

SPONTANEOUS RUPTURE OF SPL AFTER DEFÆCATION

A. W. N. DRUITT
M.R.C.S.

SURGEON, ANDREW'S MEMORIAL HOSPITAL, KINGSTON, JAMA
LATE CLINICAL ASSISTANT, SHEFFIELD ROYAL HOSPITAL

SPONTANEOUS rupture of a diseased spleen has been recorded, most commonly in malaria and less commonly in leukæmia, Banti's disease, disease, syphilis, tuberculosis, amyloid disease, kala-azar. Susman (1927) collected additional cases to hæmophilia, acute infections, typhus fever, relap fever, cystic degeneration, infarction, sarcoma, absc and hydatid disease.

The commonest cause of ruptured spleen in this coun is trauma, which causes either immediate shock or si of intra-abdominal hæmorrhage; the rupture may occur until several weeks after the accident. Jack (1925) reported a case of rupture occurring 28 days af injury. Very slight trauma, such as the flick of the fing under the left costal margin, may suffice to rupture malarial spleen—a fact made use of in certain countr by would-be assassins.

Spontaneous rupture of an apparently normal sp is much rarer. The term "spontaneous" is ob difficult to define but is here intended to imply rupt in the absence of trauma. Zuckerman and Jacobi (collected 28 cases of spontaneous rupture of a spleen, regarding 21 of these as genuine and 7 as d

In some other cases rupture was preceded by physiological effort, such as bending to lift a weight (Susman 1927), coitus (Stretton 1926), (Hubbard 1879), and labour (Schwing 1880). Burne and McMenemey (1935) reported cæsarean section splenectomy in a 16-para whose spleen had ruptu ihe stretched backwards and upwards to turn out ; eighteen months later she gave birth to her 17th

---

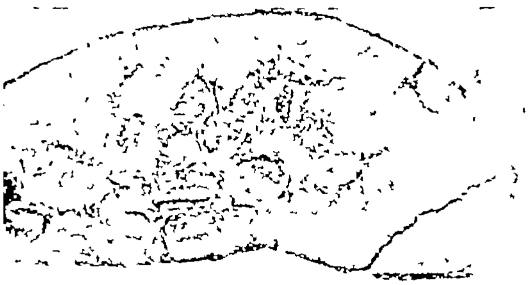
* Since the completion of this paper Abrahams et al. (1947) have published a case of porphyria with features of adrenal insufficiency. This patient's serum-chloride was 380 mg. per 100 ml. and the sodium 248 mg. per 100 ml.; she was treated with eucortone and salt.

In the case reported by Watson and Ferdeber the patient was awakened from sleep by the abdominal pain.

following case is the first reported in which e followed the effort of defæcation.

CASE-RECORD

rman prisoner-of-war was admitted to hospital on , 1945, with a history of vague indigestion for two



opical section of spleen showing hæmorrhages (just under life size).

with a sudden onset of acute pain five minutes after ion.

amination he was not much shocked ; pulse-rate 92, ature normal. His face did not have the worried ance usually seen in gastric perforations There was ike rigidity of the abdomen and much tenderness in ogastrium. The pain seemed to be slightly worse on ht of the midline. A more exact history was not d until later (see below), owing to language difficulty, iagnosis was made of perforated gastric ulcer.

tion.—Under gas, oxygen, and ether anæsthesia, a paramedian incision was made, splitting the rectus The abdominal cavity contained a little blood-fluid. No abnormality of stomach or duodenum was A small tear was seen in the liver, but this was possibly ult of too enthusiastic retraction ; it was certainly ugh to explain the hæmoperitoneum. On passing the to the abdomen, a large soft blood-clot was discovered left flank, and a soft mass was felt protruding from a n the capsule of the spleen.

original incision was enlarged parallel to the lower tal margin, thus cutting a portion of the right rectus, e whole of the left. The spleen was delivered and d. The wound was closed without difficulty and well, and the patient made an uninterrupted recovery hree weeks in bed.

stigations.—Blood-count on the morning after opera-ed cells 5,000,000 per c.mm., Hb 90%, white cells 16,700 m. (polymorphs 85%, lymphocytes 6%, monocytes 9%, ils and eosinophils less than 1%). No abnormal white ere seen. Red blood-cells appeared to be normal.

spleen was normal in size, being $3^1/_2$ in. long, 2 in. and $1^1/_2$ in. thick at its centre. The capsule on the r surface was ruptured, and from the small tear in lp a blood-clot was exuding. On cross-section the ance was as shown in the accompanying figure.

H. J. Barrie, pathologist to the Royal Hospital, Sheffield, ed: "The splenic capsule, malpighian bodies, and vessels appear normal. The pulp is for the most part cted and therefore appears very cellular, but its com-t cells appear normal. Finger-like hæmorrhages seem verse the spleen without any relation to its anatomical ure. They are all recent. The red cells are for the most bordered by normal pulp or separated from it by a r rim of fibrin. In the hilum one hæmorrhage has an zone of laminated thrombus. This hæmorrhage probably ated the others but could not have been more than a r so old, for surrounding erythrophagocytosis is very though there is considerable polymorphonuclear on. None of the hæmorrhages has caused marginal se in hæmosiderin, and the pulp contains only scanty ellular hæmosiderin. No Leishman Donovan bodies The histological picture throws no light on the origin hæmorrhages."

Events preceding rupture.—During convalescence the patient gave a few more details. For three weeks before the operation there had been small vague pains in the left loin, particularly at night, but not severe enough to cause him to report to the doctor. Two years previously, during the bombing raids on Germany, he had been hit by falling masonry, which had caused bruising of the right leg and slight concussion, but no abdominal bruising or injury. He had never had malaria or any other serious illness, and he confirmed the fact that the acute pain followed a normal act of defæcation. At the time he was not constipated.

DISCUSSION

Kehr's sign of radiating pain to the right shoulder is pathognomonic of a ruptured spleen but was absent in this case. Ballance's sign of increased dullness to percussion in the left flank, seldom shifting when the position of the patient is changed, was not looked for.

Trendelenburg (1918) stated that vomiting was a constant sign of rupture of the spleen, but it was absent in this case and in 16 of the 28 collected by Zuckerman and Jacobi (1937). Kehr's sign occurred in only 3 of their cases.

In the present case and in 5 of those collected by Zuckerman and Jacobi there was a history of indigestion before the rupture. Rupture was possibly due to increase in pressure in the portal vein.

The spleen in my patient resembled that described by McCarthy and Knoepp (1944). The pulp contained dark purplish-red circular and ovoid hæmorrhagic nodules, varying in diameter from a few millimetres to 2 cm. Histologically, a diagnosis of multiple hæmangiomata of the spleen was made.

My thanks are due to Mr. D. Brady for the histological sections, and to Mr. A. L. Watson, M.S.R., for the photograph.

PSEUDOMONAS PYOCYANEA MENINGITIS FOLLOWING SPINAL ANALGESIA

IAN M. DAVIDSON
M.D. Glasg., F.R.C.S.E.
ASSISTANT SURGEON, CUMBERLAND INFIRMARY, CARLISLE; SURGEON, CITY GENERAL HOSPITAL; AND SURGEON, E.M.S.

ACCOUNTS of meningitis following spinal analgesia are infrequent because of " a natural reluctance to report what should be a preventable happening " (Kremer 1945). But I feel that the conscientious recording of such cases is important, if only to emphasise the possible dangers of the method and keep in everyone's mind the importance of a rigid technique in asepsis both in the preparation of the syringes and ampoules and by the administrator.

Kremer reported 7 cases, 1 of them fatal. Evans (1945) described 2 fatal cases due to *Ps. pyocyanea.* More recent examples are those of Vuylsteke (1947) and the Portsmouth case (*Lancet* 1947).

My own experience is as follows. On April 16, 1945, three hernial repairs were carried out under spinal analgesia. The first patient, aged 41, made an uninterrupted recovery; the second, aged 19, developed meningitis from which he subsequently recovered; and the third developed meningitis from which he died sixteen weeks later. The details of the 2 cases of meningitis were as follows.

CASE-RECORDS

Case 1.—An air fitter R.N.A.S., aged 19, underwent on April 16, 1945, a Willys-Andrewes modification of a Bassini repair of a right oblique inguinal hernia under spinal analgesia with 3 ml. of 5% 'Planocaine' given in the right lateral position. From the evening following operation he had severe headache. There was no nausea, vomiting, or diarrhœa. On the 19th head-retraction and Kernig's sign developed. Lumbar puncture revealed a turbid cerebrospinal fluid (C.S.F.) at a pressure of 90–100 mm. of water. Examination of the C.S.F. showed 1500 polymorphs per c.mm., and culture yielded a growth of *Ps. pyocyanea*. Patient was given sulphadiazine in full doses on the 18th, and after the finding of the organism in the C.S.F. a ketogenic diet was given in the hope that aceto-acetic acid in the C.S.F. might inhibit the organism, even as 1% inhibits it in the bladder or in an open wound. On the 20th lumbar puncture was repeated and 10 ml. withdrawn. Penicillin 50,000 units was given intrathecally.

In the meantime the organism was tested in vitro against penicillin and all the sulphonamides, either alone or in combination; none made any appreciable difference to its growth except sulphamerazine. On the 27th sulphamerazine was given, starting with eight tablets of 0·5 g. and continuing with two tablets every four hours. Lumbar puncture was repeated on the 22nd, 26th, and 30th and on May 10. On April 30 there were only 129 cells per c.mm., and there was no growth on culture. On May 15, because of a tendency to leucopenia, the drug was reduced to 1 g. eight-hourly. The drug was discontinued on the 23rd and the patient, being symptom-free, was allowed up. On the 25th the ophthalmologist reported that the optic disks were clear. On June 6 the patient was discharged to his unit.

Case 2.—A private, aged 18, underwent on April 16, 1945, a Bassini repair of a right oblique inguinal hernia under spinal analgesia with 3 ml. of 5% solution of planocaine administered in the right lateral position. He had headache, diarrhœa, and vomiting after operation and was given a full course of sulphadiazine starting on the 18th. Next day lumbar puncture revealed a turbid C.S.F. under pressure, and by this time he had developed head-retraction. Examination of the C.S.F. showed 3500 cells per c.mm., mainly polymorphs, but there was no growth on culture. On the 20th lumbar puncture was repeated, 10 ml. of fluid withdrawn, and penicillin 50,000 units given intrathecally. The fluid from this puncture contained 940 cells per c.mm., and there was still no growth on culture.

Ps. pyocyanea was first isolated on May 2, but on April 27 sulphamerazine was given, starting with eight tablets of 0·5 g. and two tablets thereafter four-hourly. The dosage was modified as the white-cell count became lower and then increased as symptoms required. By May 11 there were only 14 cells per c.mm. in the C.S.F. and one colony of *Ps. pyocyanea* in serum agar. On the 23rd there was no growth on culture. The patient's general condition was, however, deteriorating, and a week later there was a further growth of the organism on culture. In spite of further sulphamerazine the clinical condition of the patient worsened, and he died on Aug. 5.

Necropsy revealed a tense dura on removal of the skull cap. Both cerebral hemispheres were flattened by hydrocephalus, but there was no pus over either hemisphere. Pus was found surrounding the medulla, pons, and inferior surface of the cerebellum. The brain was removed, and thick greenish pus was found in the lateral and fourth ventricles. There was obstruction of the aqueduct of Sylvius and foramen of Monro, with internal hydrocephalus. No abnormality was found in the thorax or abdomen.

COMMENTS

An exhaustive attempt was made to trace the source of the infection in these cases, but without success. Cultures were made from the glove powder, sterile water, and air of the theatre, but no trace was found of *Ps. pyocyanea*. A possible source of infection was thought to be the patient's skin, but cultures from the skin of the back on May 11 yielded only *Staph. albus*.

Undoubtedly the second patient died mainly because the internal hydrocephalus and basal meningitis gave no chance of drainage; but one is forced to the conclusion, already expressed by others, that meningitis following lumbar puncture with or without introduction of a solution for spinal analgesia will be avoided only by the maintenance of a scrupulously careful aseptic technique which must apply to the whole theatre.

The only other case of meningitis following spinal analgesia which has occurred in this area during several years was in a patient operated on in the same and in this case *Ps. pyocyanea* was cultured " sterile " water in a winchester jar.

SUMMARY

Two cases of *Ps. pyocyanea* meningitis spinal analgesia are described. One patient after treatment with sulphamerazine; the other

The source of the infection could not be traced in a similar case (not described here) the so-called sterile water in the operating-theatre.

Emphasis is laid on the importance of a rigid of asepsis in lumbar puncture, whether for anæsthetic purposes.

ROYAL SOCIETY OF MEDICINE

Renal Circulation

AT a meeting of the section of experimental med on Oct. 21, Dr. A. E. BARCLAY (in the absence of K. J. FRANKLIN) outlined the development of the logical techniques which have been applied to the of the renal circulation. The work originated in ments by Barnes and Trueta, who set out in determine whether protracted constriction of could cause persistent spasm of its main art tourniquet was applied to one of the hind legs anæsthetised rabbit to exert pressure on the vessels for several hours. Angiograms of both were made at various intervals after the removal tourniquet. In some animals the spasm was to the vessels of the affected limb, in others the of the other limb also were in spasm, and in one there was well-marked spasm *above* the level tourniquet. Other studies on the circulation taken at the Nuffield Institute in cats, rabbits, and sheep fœtus provided a technique suitable for demo ting all the abdominal vessels in the intact animal in later investigations. In these further tourniquet ments, by the injection of thorotrast into the ext jugular vein and by direct cineradiography, it found that prolonged application of a tourniquet thigh resulted in arterial spasm involving not only femoral arteries but also the aorta and extending ally to include the renal arteries. In such suitably timed angiography showed diminution in calibre of the renal arteries and pronounced dilat of the renal veins—by contrast the mesenteric was unaffected. The changes noted in the renal in these tourniquet experiments were reproduced stimulation of the central end of the cut sciatic Thus the constriction of the renal arteries was to be a reflex reaction to afferent impulses with efferent pathway located most probably in the nerves. Bilateral section and degeneration of splanchnics was followed by dilatation of the vessels and mesenteric artery, and in tourniquet ments performed on animals so treated these remained unaffected while the limb vessels were stricted. Finally, faradic stimulation of the splanchnic nerve yielded results closely comparable those from tourniquet experiments or after effe sciatic stimulation and gave final proof of the rôle of splanchnic nerves in the reflex vasoconstriction.

When taking angiograms during these experim Dr. Barclay explained, it was customary to two exposures at carefully timed intervals, to show thorotrast first in the renal arteries and then in the In some angiograms of the renal arteries, in tou experiments, a certain amount of the contrast med was noted actually in the renal veins. Further obs tions on this point by direct cineradiography sh the renal circuit-time much altered from the n from the control circuit-time of 2·7 sec. before the ment to 1·8–2·1 sec. during the application of the tou still further reduction to 1·5–1·65 sec. at 15 min. 5 hours after its removal. There was a correspond- astriction of the renal artery and dilatation of nal vein, and so the presence of a "shunt" or ircuit was suspected. This led to a study of the tion within the kidney to ascertain where the ircuit was taking place.

tinuing the account of this work, Dr. JOSEP A said that after inconclusive radiographic results experiment in which the central end of the cut nerve (left) was stimulated, methylene-blue was d into first the left and then the right renal arteries. sult was quite unexpected. The kidney on the ulated side (right) was uniformly stained, that stimulated side (left) showed on the surface only small scattered dye spots. On radial section the nce was much more striking—on the left side the ortex and medulla alone were stained; the outer was not stained. This gave a clue to the level short-circuit, and everything now pointed to the ing mechanism being a neurovascular reflex. fter followed studies of the intrarenal circulation roradiographic, histological, and several injection ques. By the integration of these, the complete he "lesser" renal circulations were demonstrated e latter shown to be the normal medullary circula- stained by the large glomeruli of the boundary that is, the juxtamedullary glomeruli and their t vessels, sometimes also called the vasa recta). These experimental findings seemed to indicate the kidney might be regarded as having two nally separate parts, the cortical and the lary; Dr. Trueta also stressed the high proportion recta to the loops of Henle, which suggested that a recta have a functional significance. He then d the demonstration of the circulation in experi- renal cortical necrosis; cessation of the circula- the affected outer cortex and its continuance h the juxtamedullary glomeruli to the medulla early similar to the medulla-diverted circulation miquet experiments, and in experiments on sciatic- and splanchnic-nerve stimulation. He ended by strating the formation of vasa recta vera in arterio- tic and hypertensive human kidneys by stages in a of exquisite 'Neoprene' preparations.

J. F. HEGGIE gave an account of his studies in neasurement of the renal circulation-rates in the al rabbit and in rabbits in which cortical necrosis een produced by intravenous injection of staphylo- s toxin. He illustrated (by filmstrip) the normal lar channels in the kidney and emphasised the tially glomerular nature of the circulation. From vations on the structure, volume, and number of lomeruli and on the total renal blood-flow it had calculated that the normal glomerular capillary ne was changed five times each second (if all glomeruli functioning, as possibly they were) and the velocity ch glomerular capillary loop was probably at least nm. per sec.—i.e., higher than the average capillary lsewhere (0·5–1·0 mm. per sec.)—but this was not ising in view of the fact that the glomerular laries were interposed between arterioles and the ure in them was high. In renal cortical necrosis of origin the initial lesion (with the doses employed) lemonstrated to be an inflammation of the glomeruli e strict sense, proceeding through capillary hyper- , slowing of the flow and diapedesis, to stasis in the x save in the boundary zone where the glomeruli, ased fivefold in volume, maintained an augmented at approximately normal rate (velocity). This was ar demonstration of the blood-supply to the renal ulla, and to the concerned glomeruli he had in 1941 n the name *juxtamedullary;* and from these findings ad indicated to the workers in Oxford that the short- ut they had discovered and demonstrated in vivo via these juxtamedullary glomeruli. These changes ked one extreme of a wide range; at the other were normal variations of the renal circulation, and een were alterations which occurred in a variety of litions, with varying degrees of derangement of ation and reabsorption rates, and of electrolyte and retention; these required further study.

Dr. E. M. DARMADY had studied about 1000 cases following injury or crush injury and had found certain lesions histologically which appeared to fit in very well with the circulatory findings just described—relative ischæmia in the renal cortex, congestion of the juxtamedullary area, and engorgement of the vessels in the medullary zone. He considered, however, that it was unwise to translate directly the findings in the rabbit to man at this stage, particularly as he knew from his experiments that the renal pedicle in the rabbit was very sensitive to traction and that ischæmia readily resulted.

Mr. R. H. PARAMORE was interested in alterations of the renal circulation particularly in relation to urinary secretion, to which no reference had been made. Several years ago he had reported in the *Proceedings* of the society that when the ureters were clamped the kidney became almost bloodless. He had ascribed the relative ischæmia of the cortex which occurs in eclampsia, despite the hypertension, to increasing back-pressure, which, within the kidney, brings about diminution of the renal circulation-rate and blood-flow, through the agency of the pressure of distended tubules.

Prof. H. P. HIMSWORTH had been studying the intralobular circulation of the liver in dietetic deficiency experiments and had seen a few hæmorrhages occur in the portal tracts as the initial stage of necrosis; by following the stages of these circulatory changes he had concluded that the hæmorrhages resulted from swollen liver cells damming back the blood in the portal system. The relation to the kidney was that these hæmorrhages could be produced in rats of 40–50 g. (only). At a recent meeting in New York, Dr. Baxter of the Best Laboratory, Toronto, showed pictures of the circulation in the kidney after the injection of choline into the circulation of these choline-deficient animals. There was great swelling of the cells of the tubules, and these pressing on the intertubular capillaries had obstructed the circulation and so dammed the blood back that small hæmorrhages resulted.

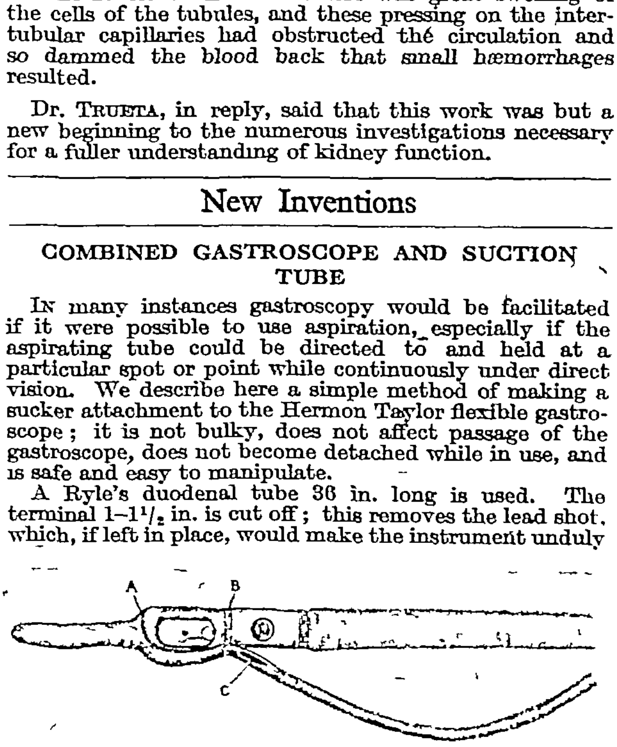
Dr. TRUETA, in reply, said that this work was but a new beginning to the numerous investigations necessary for a fuller understanding of kidney function.

New Inventions

COMBINED GASTROSCOPE AND SUCTION TUBE

IN many instances gastroscopy would be facilitated if it were possible to use aspiration, especially if the aspirating tube could be directed to and held at a particular spot or point while continuously under direct vision. We describe here a simple method of making a sucker attachment to the Hermon Taylor flexible gastroscope; it is not bulky, does not affect passage of the gastroscope, does not become detached while in use, and is safe and easy to manipulate.

A Ryle's duodenal tube 36 in. long is used. The terminal 1–$1\frac{1}{2}$ in. is cut off; this removes the lead shot, which, if left in place, would make the instrument unduly bulky. The tube is now laid alongside the gastroscope and glued lightly in place with rubber solution, such as is used in repairing rubber gloves. The terminal part of the Ryle's tube and the flexible rubber tip of the gastroscope (it is necessary to use a lamp with a rubber finger-tip and not a rounded metal end) are then firmly bound together with fine silk thread by whipping. The thread is then covered with rubber solution. A slit finger from



Combined gastroscope and suction tube: A, junction between new tip of gastroscope and lamp; B, lashing of Ryle's tube to gastroscope; C, new aperture made in Ryle's tube.

a rubber glove is then placed over the gastroscope tip and terminal end of the Ryle's tube and is glued in position, its edges being carefully trimmed to leave a perfectly smooth surface and a smooth junction between the new gastroscope tip thus formed and the lamp (see figure). The Ryle's tube is then tightly bound to the gastroscope with silk thread just proximal to the lamp, shutting off the lumen of the Ryle's tube from the holes in its end. A new hole is now cut with curved scissors immediately adjacent to the lens of the gastroscope.

It is unnecessary to attach the Ryle's tube to any other parts of the gastroscope; attempts to do so lead only to dangerous surface projections and to occlusion of the Ryle's tube. While the gastroscope is in use, the proximal end of the Ryle's tube must be kept closed with a spigot. If this is not done, each time air is introduced into the stomach with the blower some of it will escape up the Ryle's tube, tending to deflate the stomach when inflation is desired.

Some of the advantages of using this instrument are as follows:

(1) Intubation and emptying of the stomach before gastroscopy, even in the presence of pyloroduodenal obstruction, is eliminated, any aspiration necessary to obtain a clear field being done at the under visual control.

(2) Doubtful spots on the mucosa, covered by under which may lie an ulcer or erosion, can be by manipulating the hole in the Ryle's tube to and applying suction. If this fails, a syringe air can be attached to the proximal end of the tube, and a stream of air can then be directed spot and used to dislodge the mucus.

(3) In some patients who have had partial or gastro-enterostomy performed the vision is obscured by regurgitation into the from the jejunum. The introduction of more as often as not, to the formation of bubbles obscuring the field. Aspiration, continuous o mittent, will expose the stoma to view.

(4) Under various stimuli—e.g., histamine and —the behaviour of the actively secreting viewed, while at the same time specimens can be continuously or intermittently, as desired.

We are indebted to Miss Prudence Craig for diagram.

Reviews of Books

Food Poisoning

(2nd ed.) Elliot B. Dewberry, F.R.S.I. London: Leonard Hill. 1947. Pp. 246. 17*s*. 6*d*.

Food hygiene is an important part of preventive medicine, and much remains to be done in educating those engaged in food production and distribution. A good gauge of the practice of food hygiene is the true incidence of food-poisoning. Field workers constantly uncover outbreaks which the general practitioner either does not hear about or, if he does, fails to report to the authorities. Apart from the occasional deaths, these preventable illnesses cause much suffering and loss of time. For this reason Mr. Dewberry's general review of food-poisoning should be of wide interest. As he points out, food-poisoning can be caused by metals, poisonous plants, fungi, and fish, besides bacteria. Lead, arsenic, and especially zinc poisoning, which is usually caused by cooking acid fruits in galvanised containers, still occur, though less commonly. The fallacy persists that tinned foods are specially dangerous, either from the metal or from their bacterial content, though all recent evidence points the other way. At the time of year when wild mushrooms are in season, *Amanita phalloides*, with its incubation period of 6–18 hours, as well as the various species which produce a muscarine effect after a shorter time, lies in wait for the unwary gatherer. Enteric fever from eating contaminated shellfish is not as rare as it should be, but there are few cases of severe fish-poisoning in this country. Mussels have killed several people in California, and outbreaks are reported from both sides of the Atlantic. Typical cases of poisoning by the well-known poisonous plants containing alkaloids, such as coniine and hyoscyamine, are briefly described.

Bacterial food-poisoning is evidently increasing. New tools, particularly the phage-typing technique, enable us to establish the cause and to trace the source of outbreaks which in the past would have remained unknown. Poisoning by staphylococcal enterotoxin is so common and the symptoms so characteristic that the practitioner should seldom miss the opportunity to have outbreaks investigated. As Dewberry points out, much has still to be learnt about the nature and mode of action of enterotoxin but a great deal can be done to eliminate its consequences. Despite our wealth of bacteriological information about the salmonella group of organisms, present methods of controlling this type of food infection are obviously inadequate. On the other hand, only a few family outbreaks of botulism have occurred since the Loch Maree tragedy in 1922; but as long as bottling remains a national duty some householders may rashly bottle vegetables—which are more likely than fruits to contain spores of *Cl. botulinum*—and so run the botulism. Dewberry describes all of these food in a manner which will perhaps interest the reader more than the expert; but his aim is to information about food-poisoning, and so to reduc

Freud: Master and Friend

Hanns Sachs. *London: Imago* Publishing Co Pp. 192. 9*s*.

The personality of a man who threw such personality and its origins as Freud did has interest. Hanns Sachs was on intimate terms for nearly thirty-five years and here presents a and attractive picture of the man who, he says, great event and adventure of my life." Sing ness, tenacity, courage, intellectual honesty, and were outstanding traits in Freud which partly the *originality and fruitfulness* of his thought: relationship with his family and his friends complete integrity and constancy; and Dr. through a bare recital of the ways in which he saw qualities exhibited, succeeds in conveying to the his own conviction that Freud was a "great man sort that is not born in every century." Until Freud has written the biography of her father Dr. Sachs desiderates in his introduction, this book is likely to remain the most intimate account we have of an austerely devoted rev genius of our time.

Trend of National Intelligence (London: F Society and Hamish Hamilton. 1947. Pp. 35. 2*s*.)—first part of this booklet contains Prof. Godfrey Thom Galton lecture for 1946, in which he pointed to the in relation between size of family and intellectuality. second part reports a symposium in which was emph the need for more precise analysis of slow trends. lecture and symposium together throw light on a disqu question.

Physical Treatment of Injuries of the Brain (Lon *Baillière*. 1947. Pp. 96. 10*s*. 6*d*.).—Miss K. M. Hern charge of the physiotherapy department at the Mil Hospital for Head Injuries at Oxford throughout the and in this book she explains the *methods* which she f most useful in the treatment of residual paralysis and following cerebral and spinal injuries. She emphasises cardinal principle that electricity and passive move are of little value in these cases and that the patient be taught to make the best use of what neural func remains. The exercises are clearly described and illu and the great importance of rhythm in re-education of ment is emphasised. The book is of considerable inter neurologists and neurosurgeons and should be invaluable physiotherapists and medical officers in charge of rehabil departments.

Vitamin Therapy—its uses and limitations

EFFECTS OF VITAMIN B DEFICIENCY

Restricted intake of vitamin B has been shown to produce marked symptoms of moodiness, sluggishness, indifference, fear, decreased mental alertness and physical fatigue.

Factors of the vitamin B Complex have been found effective in many such cases. This, with other experimental and clinical work, indicates the value of an adequate vitamin B intake for preventing mental strain and physical fatigue and for preventing other ill effects of malnutrition which may still occur.

BEFORTISS B-complex capsules

Also available in Ampoules

Each capsule contains

aneurine hydrochloride	1.0 mg.	nicotinamide	15.0 mg.
riboflavine	1.0 mg.	pyridoxine	0.5 mg.

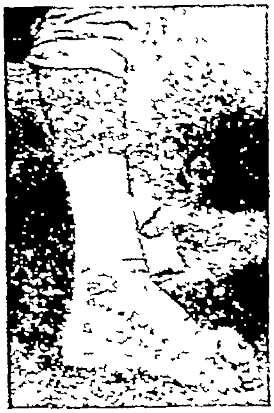

Fig. 2

Case History.

G.J. Aged 45. Grocery Assistant. The patient first attended the clinic with a deep punched-out ulcer above the left internal malleolus . . . surrounding skin inflamed. (Fig. 1).

Treatment. *August 16th*, 1946. Sulphanilamide powder was dusted into the ulcer, and calamine lotion applied to the inflamed area. An adhesive felt pressure pad was placed over the ulcer only, with a strip of 'Ichthopaste' to cover the ulcer and the inflamed area. 'Elastoplast' stirrups were applied and bandaging completed from toes upwards. (Fig.2).

Sept. 27th, 1946. The ulcer and the devitalised skin area completely healed. (Fig. 3). The patient was instructed to apply calamine lotion, pad of cotton-wool over the ulcer site, and to continue support with 'Elastocrepe' for a few weeks.

Details and illustrations above are of an actual case. T. J. SMITH & NEPHEW, LTD., Manufacturers of 'Elastoplast,' 'Elastocrepe' and 'Ichthopaste', are privileged to publish this instance, typical of many, in which their products have been used with success, in the belief that such authentic records will be of general interest.

calling for COMBINED action

Large-scale diphtheria immunization is telling its own success story . . . . and now the development by Glaxo Laboratories of an efficient whooping cough vaccine brings nearer the promise of a similar trend in the statistical [illegible] of pertussis.

For the convenience of *simultaneous* [illegible] against both these diseases, the pertussis vaccine and diphtheria toxoid have been combined as one immunological weapon. Each cc. of the Combined Prophylactic *Glaxo* contains at least Lf 25 diphtheria prophylactic A.P.T. and 20,000 million H.pertussis (alum-precipitated) The course for primary immunization comprises three injections—0.5 cc., 0.5 cc., and 1.0 cc. at monthly intervals—a feature of clear advantage to those combating these diseases.

---

vitamin D

new indications and old

New uses for vitamin D give fresh impetus to the clinical interest in 'Ostelin'—the long-established Glaxo preparation of pure crystalline calciferol. For rickets, 'Ostelin' is universally employed; but in *massive* doses, vitamin D has been used for arthritis and more recently with outstanding success in lupus vulgaris. Promise has also been shown in the treatment of other tubercular conditions such as cervical adenitis and tuberculosis of the bone.

High Potency 'Ostelin' Tablets provide an effective means of massive oral administration of vitamin D; the ampoules are for massive therapy by the intramuscular route. Any toxic reactions are readily detected and cease when treatment is discontinued—resuming therapy within the individual's limits of tolerance.

GLAXO

THE LANCET

LONDON: SATURDAY, NOV. 1, 1947

Cholera in Egypt

Monday, Sept. 22, the medical officer of health Korein, an isolated village east of the Nile delta me 60 km. west of the Suez Canal, reported lmission to Fakous district hospital of five ts with severe intestinal symptoms. Thus l an epidemic which in the first month involved nown cases, with 3230 deaths. A statement by Bey to the World Health Organisation's expert ttee on quarantine suggests that from the first yptian authorities were alert to the peril. On londay evening government officials visited rein and established that the disease was ; and next day a house-to-house search was all sick and suspected cases being sent to an on camp. Almost immediately, however, further were reported from both banks of the Ismailia ; and, although each infected area was cor- off, infection continued to spread. Its preva- is still greatest in the area north-east of Cairo it originated; Upper Egypt escaped infection the beginning of last week, and Cairo and ndria are still almost untouched.

predominance of the outbreak in rural areas is ly due to the primitive nature of village water- es. During cholera epidemics cases occasionally y contact or fly-borne infection, but the disease ally spread through water. Against such infec- an has a natural protection in the acid of his juice, which is capable of killing the ingested sms; but when large draughts of water are wed, especially on an empty stomach, the fluid ass with unaltered pH into the intestine. The f infected water was shown very clearly in the urg epidemic of 1892. In the city itself the -rate from cholera was 13·4 per 1000, while in ntiguous suburb of Altona the rate was only r 1000. Both city and suburb obtained their from the Elbe below Hamburg; but Altona, Hamburg, had an efficient filtration plant. nenace of deficient sanitation can be met only lucating the public to boil water and avoid minated food; and unhappily at least a section ypt's population is unlikely to coöperate in such res There have been accounts of ritualistic g of the air to ward off infection [1]; 27 people after drinking from a well down which the body oy had been cast; hidden under vegetables in a entering Cairo were two corpses of cholera ns [2]

olera prospers in the region of deltas; and in the delta, with its network of interlacing canals ied from the one great river, lies the threat of gthy outbreak. Here, however, history offers some comfort, for cholera has never yet obtained a permanent foothold in any country to the west of India; each epidemic has been traceable to its origin in the East, from which the organism has been conveyed by man. The route of infection in the present outbreak is still uncertain. There is no indication of an overland spread such as that which occurred more than once in the nineteenth century, when cholera reached Europe via Afghanistan, Persia, and south-east Russia. Egypt has commonly become infected by men and women returning from religious pilgrimages; but this year the epidemic began before the start of the pilgrimage season. The proximity of El Korein to the canal zone brings to mind the possibility of infection having been introduced by sea. The European epidemics of 1863–69 and of 1879–83 first reached Egypt via Bombay, Aden, and Mecca; and it was in Egypt in 1883 that ROBERT KOCH identified the cholera vibrio. A correspondent [3] has suggested that troop movements from India may have accounted for the outbreak. This to say the least is improbable, since troops are under continuous supervision and no cases have yet been reported among British military personnel. There remain, however, the possibilities of an undetected case in a ship trading with the East, and of infection having been carried by aircraft; Egypt, and for that matter England, can be reached by air within the incubation period of the disease. Cholera is one of the five infections against which the international conventions for sea and air travel are particularly directed, and the troubled state of some parts of the world should prompt redoubled attention to their observance. Whether the epidemic is now to spread round or across the Mediterranean into Europe depends on the efficacy of the measures taken by each country at its frontiers. Fortunately, efficient quarantine is an almost perfect bar to the entry of infection. Moreover, there has been no instance of a chronic cholera carrier producing groups of cases at intervals remote in time and place from his original infection, and it is now doubted by many whether an effective healthy carrier-state exists; in areas of Bengal where the disease is prevalent the vibrio, in the course of an extensive investigation, has been isolated only in close association with actual cases of cholera. Recent work suggests that earlier reports of protracted excretion of the vibrio may have been vitiated by fallacies in serological diagnosis; furthermore, isolation of the organism at intervals from the stools of cholera convalescents and contacts may result from successive reinfections without clinical symptoms. There is reliable evidence that in most cases of cholera the vibrio is not excreted beyond the fifth day although sometimes excretion continues up to two weeks or slightly longer.

Since 1902, it is said, only 5 cases of cholera, all in 1918, have been seen in Egypt [4]; and a fuller understanding of the epidemiology may emerge from observations in a country long untouched by serious outbreaks. In India Sir LEONARD ROGERS [5] had remarkable success in forecasting outbreaks, which, he said, are likely to start when the absolute humidity of the atmosphere exceeds 0·4; and it will be interesting to see whether his conclusions are confirmed in Egypt. The most heavily infected provinces are being divided into several separate sections, each under the charge of a doctor with sweeping powers. The authorities are also attempting to get each member of the population inoculated with anti-cholera vaccine. It is generally agreed that active immunisation, if repeated from time to time, is more or less effective; and it may be hoped that this impression will soon receive statistical backing when the results of a large-scale inoculation study in India are obtained. But immunisation, however effective for personal prophylaxis, will never eradicate cholera. The world can be freed of this scourge only by attack at its two sources—Lower Bengal and the Yangtse valley. The World Health Organisation, when it gets into its stride, might well set about this task through a programme of sanitation and education in these two areas. There could be no better proof of its value to mankind.

Clinical Tropical Medicine in London

Sir Philip Manson-Bahr's informative and witty presidential address on Oct. 16 to the Royal Society of Tropical Medicine and Hygiene ended with a nostalgic picture of the old Endsleigh Gardens Hospital for Tropical Diseases, in which so much of his work has been done. At this point some of his hearers must have been moved to reflect on the many vicissitudes of clinical tropical medicine in London.

Great Britain has had colonies and settlements in the tropics for nearly three hundred years, but there was no institution in this country for the systematic teaching of tropical medicine and hygiene until less than fifty years ago. Towards the end of last century Sir Alfred Jones, leader of a group of West African merchants, formulated a scheme which ultimately led to the foundation of the Liverpool School of Tropical Medicine; and about the same time, in London, Sir Patrick Manson put before the secretary of the Seamen's Hospital Society the idea of using the Albert Dock Hospital for teaching tropical medicine. Joseph Chamberlain, then Colonial Secretary, gave his warm support to the scheme evolved at the Albert Dock, and on Oct. 3, 1899, the first teaching session there began with 27 students. Both in Liverpool and in London the clinical schools in tropical medicine started in general hospitals in the dock areas, but as they developed they moved nearer to the city and university centres. In 1920 the growing London school was transferred from the Albert Dock Hospital to a separate Hospital for Tropical Diseases established in Endsleigh Gardens. Conveniently and centrally situated, close to the academic centre in which the combined London School of Hygiene and Tropical Medicine was soon to arise, the work of this hospital rapidly expanded, and it stood as a vital monument to the spirit and foresight of Manson. But the late war struck two severe blows at its very heart: first, because of the threat of bombing, it had to be completely removed to various other hospitals—which destroyed its clinical unity—and secondly most of its staff were scattered on service throughout the world. Those interested soon saw that unless this process of gration could be reversed London would be after the war to resume the contribution to t teaching, and research in tropical medicine that i worthily made since the beginning of the cent

Early in 1945 a meeting composed of represen of Government departments, Dominion and interests, the Services, learned societies, and a hospital, and other bodies concerned met and recommendations. It was agreed on the highest that a suitable hospital of some 200–300 beds be established, near and linked to the teaching school and research laboratories and f a closely knit tropical centre. Thus the teac tropical medicine would be centralised, wit association between the clinicians and those in the related academic sciences, while the tration of patients suffering from tropical d would not only increase the scope and value of c teaching but would also provide material for de or large-scale research. In addition, such a would attract postgraduates from all countries form one of the focal points of tropical m Harmonious coöperation with the other great centre at Liverpool was envisaged, while liaison various research laboratories in different parts of tropics would enable workers to be intercha Pending realisation of these plans, an attempt made to fill the gap left by the closure of th hospital by acquiring a nursing-home at 23, D shire Street, W.1, and using it as a temporary hos Unfortunately, admirable though this temp hospital has proved from the standpoint of its vidual patients, it has not room for all the ap priate cases, many of which have to be sent to o hospitals within the Seamen's Hospital Society elsewhere. Moreover, it does not possess the sp and facilities required for teaching large classes students nor for research laboratories worthy of clinical material on hand. Notwithstanding th difficulties, large classes of medical and nur students are receiving instruction in tropical disea but the waste and trouble caused by the pre dispersion of patients is considerable, and the ne for the formation of a single centre is great.

Unhappily, hope for the major scheme now bu less bright. Controls, and the need for reduc capital expenditure, seem to make the possibility building remote, while uncertainty about the ex pattern of our future health service and econom status possibly has a restraining influence on plann and development. Nevertheless there are cog reasons for pressing on without further delay Though tropical disease must be studied in th tropics, it must also be studied, against an academ background, in major scientific centres, of whic London is outstandingly suited to the purpo Today the greater movement of peoples and th rapidity of modern transport are bringing about virtual contraction of the world that is bound t increase the interest taken in tropical diseases an necessitate further study and instruction in trop medicine. Likewise the development of new agri cultural and commercial undertakings in the Coloni whose importance for the welfare of Colonial peopl and for the very survival of our Commonwealth needs little emphasis, and the obligations that w to the Colonial peoples, make the restoration rery facility for treatment, research, and teaching ropical medicine a matter of true urgency. Like **Philip Manson-Bahr**, we trust therefore that e way will be found to enable the principal city he Commonwealth to resume its proper part in ancing and disseminating knowledge of clinical ical medicine.

Present Status of Disc Surgery

; 1934 **Mixter** and **Barr**[1] reported a series of atients operated on for prolapse of a lumbar interebral disc. If their observations were not novel, ny rate they marked the beginning of an epoch. y thousands of operations for disc anomalies have ı performed during the last decade by general eons, neurosurgeons, and orthopædic surgeons world over; and, as long-term results accumulate large series are recorded, it is possible to put this k in its right perspective. Yet the subject is young enough for surgeons to disagree widely often dogmatically on points which seem fundaıtal—such as the precise indications for operation; ther one should be as ready to operate for low k pain as for sciatica; the best surgical exposure; living pathological appearances of the exposed , and how much of it should be removed; and, least, the desirability of spinal fusion. These other matters are dealt with by **Murray coner** in his Hunterian lecture summarised in issue, and were discussed at the annual ting of the American Orthopedic Association last r.[2]

he difference between personal approaches is able. That enthusiast and individualist, the late **lter Dandy**, performed 843 operations in four rs, using a peephole interlaminar approach by ioving the ligamentum flavum on one side only.[3] tried to remove the whole disc and believed that vertebral surfaces left to approximate might spontaneously. He described the "concealed " as a common and important lesion; he regarded elography as unnecessary and unhelpful, and never ried out deliberate spinal fusion. On the other ıd, **Falconer**, another neurosurgeon, often uses elography and favours routine wide laminectomy. agrees on the common finding of an "intermittent lapse" equivalent to **Dandy**'s concealed disc— which is not obviously abnormal but is soft to the ıch and may be made to bulge by extending the ne. He does a very radical curettage from both es of the theca and is also entirely opposed to ion. In this country **Burns** and **Young**[4] have ten the increasingly accepted views that most es of low back pain and sciatica, together or)arate, are the result of a prolapsed disc; that elography is often useless and deceptive or actually rmful, so it should be done only when a rarity like auda equina tumour is suspected; that the neuroical picture is of no help in localisation; and that ıny cases will be missed unless the routine procedure a wide laminectomy with inspection of both 4th and h discs.

The question of spinal fusion, on which **Burns** and **Young** seem to have said nothing as yet, urgently needs clarification. The extensive laminectomy required for an adequate operation is bound to weaken the back. Moreover, the chronic derangement of an intervertebral joint which precedes the operation, even if it is not exacerbated by removal of the disc, may be enough to cause persistent low back trouble in the unfused spine during the years that follow. In some cases fusion must be called for, but the selection of these cases needs much care. One reason for neglecting fusion is given by **Barr**,[5] who remarks that "certain neurosurgeons . . . have been so impressed by the obvious relief of the patient's acute sciatica that they have failed to look carefully for late evidence of a mechanically unsound back"; this comment applies to all who are concerned merely with the short-term relief of the disabling symptom. **Barr** thinks that as technique improves a spinal fusion will be done in every patient at the time of laminectomy, and **Steindler**[6] is in general agreement with this view, because there is a significant rise in the percentage of cases permanently relieved of back symptoms when fusion has been performed. **Love**,[7] another of the pioneers in this field, would restrict the indications for fusion to cases with definite evidence of lumbosacral instability. An unspoken objection to fusion which must weigh heavily with the surgeon is that the standard orthopædic procedure requires three months in a plaster bed and protracted support and reablement thereafter. The laminectomy alone is such a common operation nowadays that there is a natural temptation to save hospital beds by declaring that fusion is unnecessary—it would, indeed, be impracticable. As was said in these columns two years ago,[8] what is needed is a revolutionary method of securing rapid stable fusion, and the Bosworth clothes-peg graft was then put forward as such a method. **Falconer** gave up having alternate cases grafted by his orthopædic colleagues because the grafts often failed to fuse to the spine, and it may well be that the standard orthopædic procedure is not only a long job but is not a fusion. Merely to slip a cortical graft on either side of the spinous processes without the most careful preparation of the bed will not suffice, and apparent success may be due only to fibrous scarring in the soft tissues of the low back. **Barr** and **Steindler** both recommend the Bosworth operation, which gives rigid fixation of the spine with no more than the usual three or four weeks in bed, and without the need for a plaster jacket or other support. This H-shaped graft, cut from ilium or tibia, is wedged tightly between the 4th lumbar and 1st sacral spines while they are held apart in acute flexion, so it is firmly locked in place when the spine is again extended.[9] There seems to be every reason for running properly controlled series in the larger orthopædic and neurosurgical centres, doing fusion in this or a similar way in alternate cases. Then, in five or ten years' time, we shall know whether fusion is necessary or not.

THE NEW FOOD CUTS

A WEEK ago Sir Stafford Cripps, in outlining the measures projected by the Government to save dollars, announced a further reduction in our expenditure on foods imported from dollar countries. The only rationed foods immediately affected by this reduction are sugar and eggs. The weekly sugar ration, which was raised from 8 oz. to 10 oz. a month ago, reverts to 8 oz., and there is to be a saving on imports of Canadian eggs, which will severely restrict the supplies to bakers, though the allocation of shell eggs to the public in the coming year is expected to be 66 per head compared with 58 last year. Meat remains at 1s. and bacon at 1 oz. a week. Sir Stafford Cripps promised that every effort would be made to offset the reductions by increased imports from soft-currency countries. But if these attempts fail the effect would be to reduce the average calorie intake per head of the population from its present level of about 2870 a day to 2700.

This is a significant fall, and it was not clear from Sir Stafford's speech how it will come about. Presumably his calculations include among the "other changes brought about for quite other reasons" the likely reduction in potato supplies consequent on the poor harvest. The average of 2700 remains above the requirement level estimated in the recent Ministry of Food white-paper,[1] which was 2550; but the reduction will bring us uncomfortably near to that basic level, and there will be an increasing danger that where distribution is faulty some will not get enough to maintain their health and efficiency. This is particularly likely in the "family pool," where the mother is apt to deny herself for the sake of the wage-earners and children, and cannot compensate for this by getting food at a restaurant or canteen.

COMPATIBILITY OF ANTIBIOTICS AND STYPTICS

THE compatibility or otherwise of the antibiotics and the styptics—two groups of substances often used simultaneously in surgery—is clearly of practical importance. One would have expected to see the subject thoroughly investigated as part of the routine study of the new styptics before their release for general use. Yet, judging from the published work, the investigations seem even now to be incomplete.

Fleming and Fish[2] have studied the effect of locally applied sodium penicillin on the coagulation of blood. They find in oral surgery that sodium penicillin powder interferes both with clot-formation and with the maintenance of the firmness of a previously formed clot. Their results were much the same with commercial sodium penicillin and with the lately developed pure crystalline salt. Blockley,[3] on the other hand, reports that calcium penicillin in combination with sodium alginate, in powder form, locally applied in the same type of case, is a rapid and satisfactory styptic which also exhibits the known action of penicillin. Correll and Wise[4] have investigated the stability of penicillin, streptomycin, and thrombin in the presence of two styptics developed in the United States—gelatin sponge and oxidised cellulose. They find that oxidised cellulose ('Oxycel') rapidly destroys thrombin and penicillin, whereas streptomycin is unaffected by it. Gelatin sponge has no deleterious effect on either penicillin or streptomycin. The penicillin which was used in their experiments was the calcium salt. Their observation on the destruction of thrombin activity by oxycellulose corroborates the earlier findings of Seegers and Doub,[5] and they agree with workers that the destructive effect of oxidised is due to its acid reaction, which can be corrected sodium bicarbonate. This may explain why other find that oxidised cellulose and penicillin are co

It is not easy to link up even the few in that have been made on these lines. Some workers used only sodium penicillin and others only penicillin, and different methods of assay have adopted. There is clearly a need for exact studi these compatibilities which will tell the surgeon c sively whether he can use the various substances to It might further be of interest to find out how the of antibiotics and styptics is affected by the changes in pH level taking place in extravasated clot, and tissues during healing under various met with in practice (e.g., in the presence or a infection); and to decide the optimum pH fo different substances. More information on the or anticoagulant mechanisms involved would also welcome.

MODERN EDUCATION OF THE DEAF

DEAFNESS and partial deafness are among the which can be mastered. Children born deaf or be deaf early in life often make a poor start in learnin overcome their disability, either because it is not noti in good time—a child with high-tone deafness is of thought to hear normally by his parents and fri —or because their parents think there is no way of them until they reach school age. In these last week, Mr. A. W. G. Ewing, PH.D., and Mrs. Ewing, M.SC., outlined the principles of home tra adopted experimentally for such children referred the research unit at Manchester University. The th is developed more fully in their book, *Opportunity the Deaf Child.*[6] This training is an exercise in for the parents. The mother especially must learn think in terms of the child's experience as co with that of the normal child, and to supplement deliberately. The Ewings have found that, given suitable opportunities, some children begin learning to lip-read when they are even as young as eighteen months; and some are trying to say words when they are still under two years. To do this they must have plenty of chances to see the mother speaking.

The mother begins with routine requests which call for the child's coöperation; thus at bath-time she always says "Give me the soap," "Bring me the towel," "Stand up," and other appropriate things, until he is doing them quickly in whatever order they are spoken. Then she begins to speak familiar words in new situations: she tells him to "stand up" at times other than bath-time, or gets him to fetch the soap when she is washing up. The next stage is the learning of new words, and this depends on the interest she has roused in the child; he begins to point at objects and to watch for their names on his mother's lips. All deaf children babble at first, and they must be encouraged to use their voices, for if they once fall silent it is difficult to get them to start speaking. The mother should always look pleased when the child makes sounds, and especially when he tries to speak words, though she should not attempt, the Ewings think, to teach him to say the words properly —that is a job for a trained teacher of the deaf. The deaf child's chances of seeing speech cannot compare in number with the normal child's chances of hearing it, because the normal child hears speech going on around him even when his eyes and hands are engaged on something else, whereas the deaf child must interrupt his pursuits to watch his mother's face. His progress thus largely depends on her ingenuity in creating opporities for him to see her speaking, her perseverance, her ability to secure his interest. His early years of ning are thus very much a joint affair.

o learn to speak is much more of an undertaking n to learn to lip-read; and many deaf people who lip- d easily enough place their friends at a disadvantage speaking barely intelligibly. Their relative failure due in part to the soft monotony of their tone; and ew equipment devised by the Bell Telephone Labora- es in America, and described in a new book,[7] may help anced deaf students to overcome this difficulty. By ins of a cathode-ray translator, luminous patterns peech are thrown on a screen and move across it at te which allows them to be identified. The patterns striking, divergent, and reasonably easily learned. y are *phonetic symbols*: thus the words "one" "won" produce the same pattern, and another tern gives "two," "to," and "too." Speech can ily be read off by anyone who has learned the terns. By speaking back what he has read, the deaf dent should be able to compare his own pronunciation h that of the model, and so correct it. Moreover, instrument gives some indications of pitch, and if e can be developed more fully they should help the f person to modulate his voice according to normal es and inflections. The device is clearly only suitable for anced training at present, and in any case is still in the perimental stage; but it offers promise for the future.

HE EPIDEMIOLOGIST AND CHRONIC DISEASE

LAST spring, at a conference held by the New York demy of Medicine, Dr. J. W. Mountin, of the U.S. blic Health Service, chided epidemiologists for their occupation with acute infectious disease—their "Broad reet Pump fixation"—and appealed for greater tention to the chronic disorders. Prof. A. D. Langmuir, Johns Hopkins, returned to this criticism at the recently ncluded meeting of the American Public Health sociation, and discussed the reasons why progress has en slow. The epidemiologist, he said, is concerned ith all people in defined universes, both the sick and e well, in relation to each other and to their environ- ent. In all types of disease the epidemiologist wishes count cases accurately, both manifest illness and apparent disease; he needs to follow the dynamic ow of these cases through his population; he wishes determine the many selective factors, such as age, x, genetic background, susceptibility, immunity, and vironment, that may influence this dynamic process. acute epidemic disease simple incidence and mortality tes may be a sufficient basis for such investigations nd results may often be quickly obtained. In the ronic diseases, though the essential principles of study main the same, the time-factor conditions and compli- ates every method of inquiry. The determination of cidence-rates may be extremely difficult because the rcumstances of onset are often obscure. Discovery tes and prevalence ratios must often be substituted. erson-years analyses and modified life-table procedures ay need to be employed. Long-term follow-up is ecessary. And the problem of the index case is always resent to plague the investigator.

Professor Langmuir illustrated these difficulties by a onsideration of rheumatic fever, a typical chronic isease, where, despite innumerable inquiries, little in he epidemiology—or ætiology—is well enough established o find general acceptance. The opportunities for study evertheless exist in the epidemics which arise from ime to time in military camps, in food-borne epidemics f septic sore throat, and in institutional outbreaks of treptococcal infection. The rheumatism schemes (much nfluenced by the example of the London County Council and now, if slowly, being developed in America) should also promote much-needed epidemiological investigation. Rheumatism registers, accurately kept and up to date, recording all cases occurring and recurring through the years and related to a defined and measurable population at risk, can, for the first time, provide the material needed for examining the spread of rheumatic fever through a community. Such morbidity statistics are incomparably more effective tools for the epidemiologist than hospital and clinic data derived from an unknown and biased population sample, or the results of static surveys of small sections of a population, or studies confined to rheumatic families.

Not content with this extension of the field of epidemiology, Professor Dublin, of Long Island, pleaded for the *application of epidemiological principles to rheumatism schemes* as well as to rheumatism—to the explanation why, with the need so demonstrable, some communities have comprehensive programmes and many do not.

SEXUAL ABNORMALITY AND THE LAW

THE great bulk of sexual aberrations do not concern the law; but those which do—notably exhibitionism and homosexuality—arouse in many people, doctors and lawyers not excluded, so much conscious and unconscious prejudice that the subject is not approached with proper detachment. In an address originally given to the Medico-Legal Society last year, Dr. Edward Glover[1] argues that abnormal sexual conduct needs suitable psychological observation and treatment, and that no other form of treatment has the slightest chance of doing good. Most of us will agree with him; but we have to recognise that the law is concerned with the well-being of society rather than that of the individual. Dr. Glover admits the difficulties of legislating for the kind of sexual offences which include, for example, assault on unknown persons: unless the offenders can be rapidly cured, society must be protected by their segregation, even though they might be treated more successfully at home or at a clinic. But he urges that every sexual offender without exception should be psychologically examined and given the opportunity of receiving psychological treatment; and that preferably both examination and treatment should be carried out by medical psychologists who are not officially connected with the court. Whenever possible the patient should be allowed to live at home, whether on probation or not, and encouraged to follow his usual work. If in the public interest it is necessary to segregate him, he should be put into an institution where he can have expert psychological aid—e.g., in an inpatient psychiatric centre. Even in favourable cases, suitable for treatment at home, immediate recovery cannot be expected; it is in the nature of compulsions that even under treatment they are liable to be repeated. The courts, Dr. Glover thinks, too readily assume that because an offence is repeated "the case is to be written off as a failure suitable only for condign measures of punishment." Good results are to be hoped from placing the patient in a county foster-home within easy reach of a psychiatric centre; and an ascending scale of supervision could be drawn up, from probationary control up to temporary segregation.

There is much to be said, in Dr. Glover's opinion, for reforming the present system of charging sexual offenders: they could more suitably be charged with offences against public decency, and bound over on set terms for treatment and supervision. Subsequent offences would then constitute contempt of court, the penalties for which would be suspended *until all efforts* at treatment had failed.

APPLIED PHOTOGRAPHY

TION OF THE PHOTOGRAPHIC DEPARTMENT TO THE TEACHING HOSPITAL

PETER HANSELL
M.R.C.S., A.R.P.S.
the Department of Medical Photography, Westminster Hospital

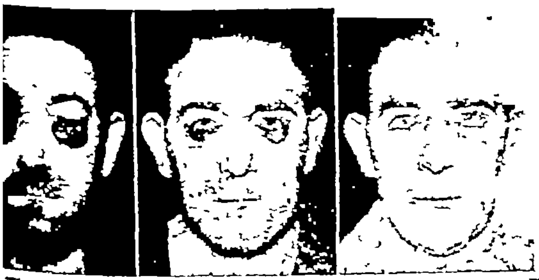
ROBERT G. W. OLLERENSHAW
B.M. Oxfd, A.R.P.S.
From the Department of Medical Photography, Manchester Royal Infirmary

r year the state of medical photography as it
xisted was reviewed (Hansell 1946). Today the
n has materially altered and many new depart-
are arising. In some hospitals the enthusiasm
ant on the establishment of a photographic unit
ring; in others it is declining; in a third group,
unately all too small, it is undergoing an evolu-
y process consequent on a growing understanding
real function of such a unit within the parent
anity. This paper is directed to the first two
, lest their energies be diverted into channels
y easy but ultimately barren.

inauguration of a medical photographic depart-
is probably brought about by a realisation of its
ng potentialities. This being so, the future must
eguarded by ensuring that it is staffed by *experts.*
nstitute of British Photographers has devoted a
n of its Final Examination to medical photography,
t it should soon be possible to recognise the expert
alified medical photographer just as it is now
le to recognise the qualified physician or surgeon.
important, however, to ensure that ultimate
l, even though indirect, should not be exercised
a merely technical level, for the potentialities are
usly wider than this.

s fairly easy to see how false steps may be made.
of the hospital staff will never use the department;
will probably allow their enthusiasm to outweigh
judgment, and their requests will too often fall
he "clinical rarity" or the "remarkable recovery"
; yet another group will use the department for
production of purely personal material either for
cation or for their private memoirs. To the new
rtment every request brings at least the encourage-
of recognition. It is only when unthinking
nds are continually made at the expense of valuable
d and teaching material that frustration and an
matic technical service appear.

e are concerned here with those functions of a
ographic unit within the teaching hospital which
to us to be of chief importance. Omissions cannot



Three of a set of six serial records showing the progress of an arteriovenous aneurysm (cavernous sinus).

but be numerous. To quote from a letter from the United States:

> "At a recent A.M.A. convention . . . the pictures fell into only four of the forty-four medical photographic techniques. . . . If this use can be made of four techniques, there are still plenty of endeavours to encourage along the lines of the other forty."

A fully established medical photographic department has two primary functions: (1) the production of routine record photographs of the highest quality; and (2) the adaptation and application of those records to medical education in its widest sense.

ROUTINE RECORDING

Many processes fall under this heading. First, though not foremost, the rarity. There is a place for this type of record; it is indeed very necessary for the publication of unusual cases, and there will inevitably be places in the curriculum when conditions are mentioned whose rarity involves an absence of clinical material. The indications for this type of record are therefore fairly well defined; they should, however, form only a small proportion of the total.

The mainstay of recorded material will be the normal or usual type of case. Suitable cases should be recorded before, during, and after treatment; for, apart from increasing the available teaching material, the photographs provide a record of progress which can rarely be conveyed with comparable accuracy by the written word. An example of this type is seen in fig. 1.

True serial photographs form a subdivision of this group. These differ from the records just described in that an attempt is made not only to produce strictly comparable pictures but also to introduce a clinically significant time-interval between each. Whereas the former aims primarily at tangible material for future use, the series now under consideration is of use in the direct assessment of progress and may have an influence on treatment. The following two examples will illustrate this point:

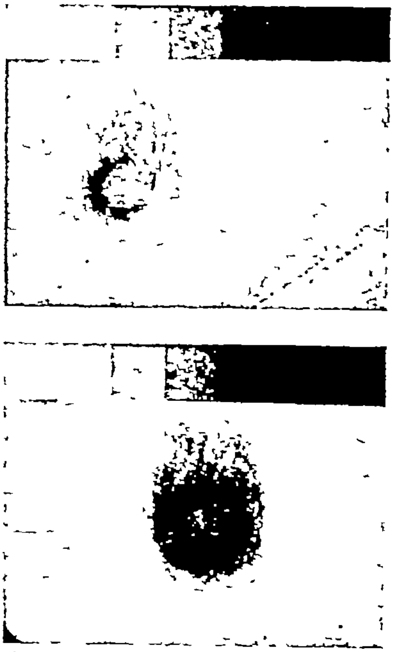


Fig. 2—Œstrogen therapy: pigmentation changes of nipple in six weeks.

(1) *Œstrogen Therapy.*—Œstrogens are now widely used in the non-operative treatment of malignant disease. It has been noted that a side-effect is progressive pigmentation, especially of the areola.

At the Christie Hospital, Manchester, possible correlation of this effect with tumour response is being investigated. Annotations being unreliable, the areola is now photographed at each attendance, a stepped density wedge being included in the picture area.

Prints are filed with the history, and the negative is measured on a densitometer, a note being made of the step of the wedge corresponding to the image of the areola.

ECONOMICS OF PUBLIC HEALTH

A PLEA for priority for public-health services—especially those that maintain and raise physical and mental fitness—was made by Dr. F. Hall, M.O.H. for Lancashire, in his presidential address on Oct. 23 to the Society of Medical Officers of Health. He quoted with approval the remark of the Working Party on Nursing that we must "ascertain the optimal effort that needs to be devoted to preventive and curative services respectively." The passing of the National Health Service Act, he said, is a recognition of the advances made in all branches of medical science, "and in one sense may be regarded as a compliment to the profession"; but its emphasis, he feels, is on medical treatment rather than on public-health measures. However, he foresees that when the expense of treating sickness in hospitals and other institutions is no longer masked by gifts, either of money or service, but appears publicly in the nation's accounts, the administrator will pay more attention to preventive methods, and there will be more likelihood of these being intensively applied both in the medical field and in home and factory.

Today, said Dr. Hall, there are special reasons why we should develop means of improving the health of the people, and their productive capacity. But even when our immediate economic difficulties have been overcome there will still be problems, arising from the effects of two wars and the ageing of the population, which it will be hard to solve unless the public health is raised to a far higher level than now obtains. While not wishing to underestimate the importance of providing for members of the community who become unfit by reason of age or infirmity, he urged that their care and welfare "depend in the long run upon the soundness of the national economy, to which a high standard of public health makes the most valuable contribution." Of the measures proved useful for preventing ill health some can be carried out by central authorities, but the majority demand local investigation and personal contacts.

The appointment of the first medical officer of health a hundred years ago was, in Dr. Hall's view, a business proposition; and he clearly believes that it is through Duncan's successors that medicine could make its greatest contribution to the nation's economic well-being.

THE NOBEL PRIZEMEN

THE Nobel prize for medicine for 1947 is shared between Prof. Bernardo A. Houssay, of Buenos Aires, and Prof. Carl F. Cori and Dr. Gerty T. Cori, of the department of biochemistry, Washington University, St. Louis.

The value of Professor Houssay's work is recognised by all interested in the problems of the endocrine control of metabolism in general and of carbohydrate metabolism in particular. It is now over twenty years since he first demonstrated the importance of the pituitary gland in carbohydrate metabolism, and his observation that removal of the anterior portion of that gland reduces the severity of experimental diabetes mellitus was responsible for a rapid advance in our knowledge of the metabolic defect in diabetes. Before Houssay's experiments it was widely accepted that the fully depancreatised dog could combust no carbohydrate at all, since it was believed that insulin was essential for any oxidation of carbohydrate. Houssay's experiments demonstrated in a straightforward manner that carbohydrate oxidation can take place in the animal body, in the apparently complete absence of insulin. Furthermore, his demonstration that the hypophysectomised-depancreatised dog (the "Houssay" animal) can survive much longer than the dog from which the pancreas alone has been removed, revealed an antagonism between the effects of anterior-pituitary extract and of insulin. Subsequently he and his school, and also other investigators, were able to induce a temporarily diabetic condition in animals treated with anterior-pi extract, and this has again led to fundamental adr

Dr. and Mrs. Cori have worked for many years field which has now merged to some extent with studied from a different angle by Houssay and his Since the early 1920's the Coris have pursued the gl molecule in its peregrinations round the animal into glycogen, into lactic acid, into hexose phosp and into many other intermediary compounds. demonstration of the in-vitro synthesis of glycogen of starch from glucose-1-phosphate by approp enzyme systems was a most useful contribution in field, and more recently they have shown the an nistic influences of anterior-pituitary extract and i in the formation of the glucose-6-phosphate from gl in vitro under the action of the enzyme hexok This demonstration has gone a long way towards viding the explanation in terms of enzyme syste the observations of Houssay and others on the an nistic action of anterior-pituitary extracts and of i and has opened a new approach to the action of horm on enzyme systems in general.

WORLD CONGRESS ON MENTAL HEALTH

THERE have already been two world congresses mental health: one at Washington in 1930, and other in Paris in 1937. The third congress, to be hel London next year from Aug. 11 to 21, has been des on ambitious lines, and will, it is hoped, attract 3000 people from over fifty countries. The diffic of reaching this country may be eased by the support promised by UNESCO and the World H Organisation.

The congress will embody international confe on child psychiatry and medical psychotherapy (Aug 15) and on mental hygiene (Aug. 16–21). The th will be, in the first conference, foundations of m health in childhood; in the second, guilt; and the third, mental health and world citizenship. congress committee, headed by Dr. J. R. Rees, is exe itself to ensure that the communications on this topic shall represent all shades of opinion in each coun Sociologists, psychologists, educationists, and oth are being invited to participate; and already discu groups, or preparatory commissions, have been set in this country and in North America to synth different individual views. The work of these c missions is coordinated from *London by* means monthly digest of activity in all countries. The orga hope is that international comparisons will lead t clearer understanding of the social relationships bearing the well-being of the individual and of society. Info tion may be had from the congress office at 39, Q Anne Street, London, W.1.

NEGOTIATIONS WITH THE MINISTER

ANSWERING a question in Parliament last week Minister of Health explained that he has not yet the Negotiating Committee but intends to do so soo Arrangements for the National Health Service hav been discussed with officers of the Ministry; but the committee will now present a statement to the Minist himself. A meeting with Mr. Bevan has been arranged for the week after next, and it is expected that t committee's statement and the Minister's reply will be published shortly afterwards.

THE death is announced on Oct. 24 of Lieutenant-General Sir HAROLD FAWCUS, director-general of Army Medical Services from 1929 to 1934, and director-general of the British Red Cross Society from 1934 to 1938. He was 71 years of age.

THE next session of the General Medical Council will be held on Tuesday, Nov. 25, at 2 P.M., when Sir Herbert Eason, the president, will take the chair.

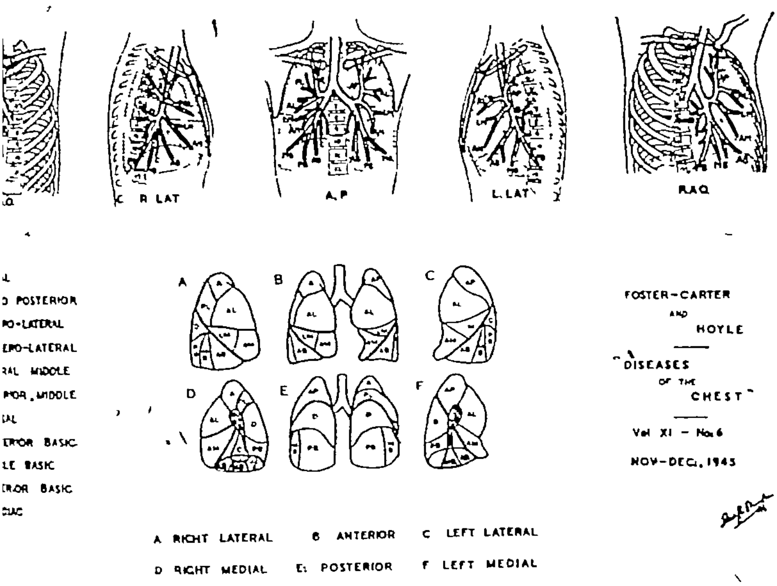

Fig. 5—The segments of the lungs. Mass-produced reflex print for notebook illustration.

licine. - It is still rare to find good use made of
m medical schools (fig. 3). Only in large institu-
ich as the Wellcome Foundation, does the matter
o have been given much thought; possibly the
nt magnitude of the task has been frightening.
exhibitions and displays are widely known; yet,
gh the same principles apply, the teaching com-
es have lagged. A tradesman exhibiting his
calculates that a potential customer will pass his
in a moment, and his display is planned accordingly;
f only one of his large slogans is remembered he
l satisfied. Similarly the essential elements of
medical display are clarity and simplicity. The
is to stimulate the appetite, not to satisfy it.

ary Card.—Closely comparable and often using
me tricks of showmanship, these are displays in
ture. An extensive set of photographs can be
ted on large cards to supplement the necessarily
d illustrations of the textbooks (fig. 4). These may
rn themselves with single cases but can well be
osite, using photograph, radiogram, micrograph,
am, and so on. They are placed in the library
e student to study alongside his textbooks.

ebook Illustrations.—A good department should be
to produce batches of illustrations for issue to
nts. Prints or reflex copies can be produced
y and cheaply from existing material. Where very
line copies are required the Gestetner "Gestefilm
Process" has been used with success. Photo-
ic reproduction is especially useful for the illustra-
which is too elaborate for rapid individual copying,
is likely to show its greatest value in advanced
raduate teaching (fig. 5).

ntern Slide.—The $3^1/_4$ in. square transparency is so
iar that it need hardly be mentioned. It has
its disadvantages compared with the miniature
square slide. Apart from the rapidity and economy
which the latter can be made, their small size and
ht and their greater relative strength cannot be
red. The large slide cannot yet be abandoned for
lay, since its image is large enough to be examined
an illuminated panel, but mechanised projectors
promised for the small slide; and, when these are
ily available, the large type may well disappear.

Filmstrip.—The Royal Society of Medicine recently discussed the use of filmstrip in medical teaching. Other articles (Hansell 1947) have appeared in the journals, and it is unnecessary here to do more than attempt to rectify certain misconceptions. Conservative criticisms are often levelled at filmstrip, which, quite unreasonably, are not raised in connexion with motion-picture film. A good filmstrip is scripted and produced along lines strictly comparable with those of a film, yet the critics object to the rigidity of filmstrip, forgetting that far less effort is involved in alterations of sequence in a strip than in recutting a film. The close technical connexion between filmstrip and the miniature slide is overlooked; and, unless they are considered together, artificial limitations will be ascribed to one or the other. With a growing understanding of these media, 35 mm. technique promises to play as important a part in our medical teaching as it already does in the United States.

Motion Picture.—Reference has been made to the film as a recording medium. When a recorded case is dismissed, not only have the films intrinsic value for teaching but selected frames can be enlarged and either filed with the history or used to illustrate published work. Fig. 6 shows the extremes of movement in a case of slipped femoral epiphysis. Under such conditions photographic quality of the prints is not good, but they are of value when the film itself cannot be projected (Ollerenshaw 1938). As clinical material accumulates, addition of suitable continuity sequences, caption, and diagram makes possible the building up of complete teaching films (Ollerenshaw 1939, 1947).

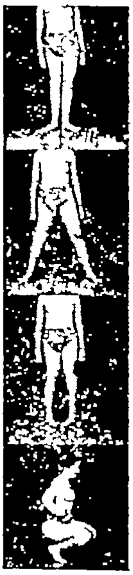

Fig. 6—Frames from a 16 mm. motion picture case-record: extremes of postoperative movement in slipped epiphysis.

THE MEDICAL ARTIST

Although not photographic, the work of the draughtsman is germane to the discussion. The medical artist is a most important member of the team. Many teachers favour this method of illustration, for unwanted detail may be eliminated with comparative ease, and a drawing may embody facets of several cases. If the artist works alone he may have to work from rapid and inadequate sketches, with much consequent revision, and it can be to his advantage to collaborate with the photographer in the production of a series of small key-prints from which he can work at leisure. The draughtsman has a very definite place in the production of teaching-aids; in the layout of displays, in the production of continuity frames for filmstrip, and in the supervision of animation sequences for motion pictures his essential value to the department will not be overlooked by his colleagues.

SUMMARY AND CONCLUSION

Photography is playing an increasingly important rôle in the medical sciences. So far, few teaching hospitals

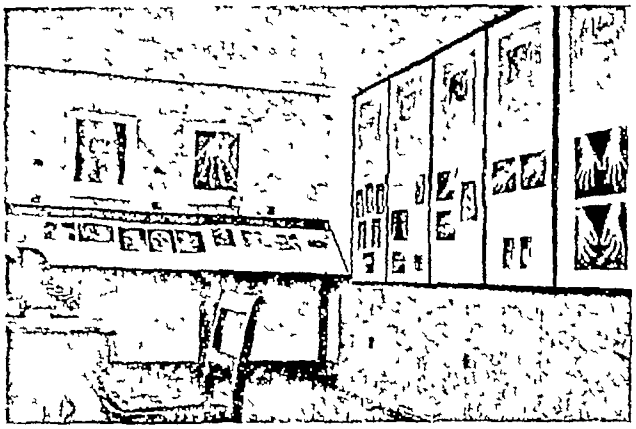

Fig. 3—Static display.

Fig. 2 shows two such records at an interval of six weeks: the change in pigmentation is not only obvious but is also measurable with reasonable accuracy.

(2) *Radium Workers' Survey.*—Accurate assessment of early changes due to radiation is of importance to workers who pack and handle radium and radioactive substances.

Recently a half-yearly survey of such workers was started at Westminster Hospital, for human fallibility has made it almost impossible to describe in words any but fairly obvious changes. The process is essentially slow, and time tends to erase the visual memory.

Scale records of the dorsal and palmar aspects of the fingers are made, attention being paid to the rendering of fine detail. A series of six-monthly records enables the clinician to detect minor atrophic changes.

Written notes are also kept, and it is interesting to note that a few cases were thought to have progressed, when in fact inspection of previous photographs showed that they had not. Workers were not therefore involved in a change of employment through the unreliability of memory and clinical notes.

Other uses for routine recording will doubtless suggest themselves to the reader.

Motion pictures are of the greatest value in assessing the progress of cases in which movement is involved; their appeal is thus mainly to the orthopædic surgeon and the neurologist. Periodic records are spliced together for routine checking while the patient is under treatment, and the resultant condensation of time conveys an impression of progress which cannot be approached either by the most perfect clinical notes or even by still photographs.

FILING

Attention has been drawn elsewhere to the important subject of filing systems; passing reference has been made to the subsequent use of records in teaching, and it follows that filing forms a link between pure recording and education. The strength of this link will be reflected in the second function of the medical graphic department—the production of teaching

In view of previous publications (Hansell 1946, photo" 1947) it is not intended to discuss the pr great length. Files or registers will be needed for reference, but such systems should not become so in that a change of directorship will involve breakdown. punch-card system was adopted by the Services of its speed and flexibility, but it is expensive to and, if it is used, the coöperation of the teaching should be sought so that initial planning should adequate for the future. It has the added adv that it can embrace all material in satellite s which are themselves constantly undergoing (Donnison 1947).

PHOTOGRAPHY IN MEDICAL EDUCATION

A department capable of recording, and of cl its records, having been evolved, the question of in medical education arises. In the following the files of records are considered as raw materi indications are given for the use of this material the minimum of additional labour. Successive involve an increase in technical processes and there in expenditure of time and materials.

Display in teaching has been widely discussed educational literature, but without much direct refer

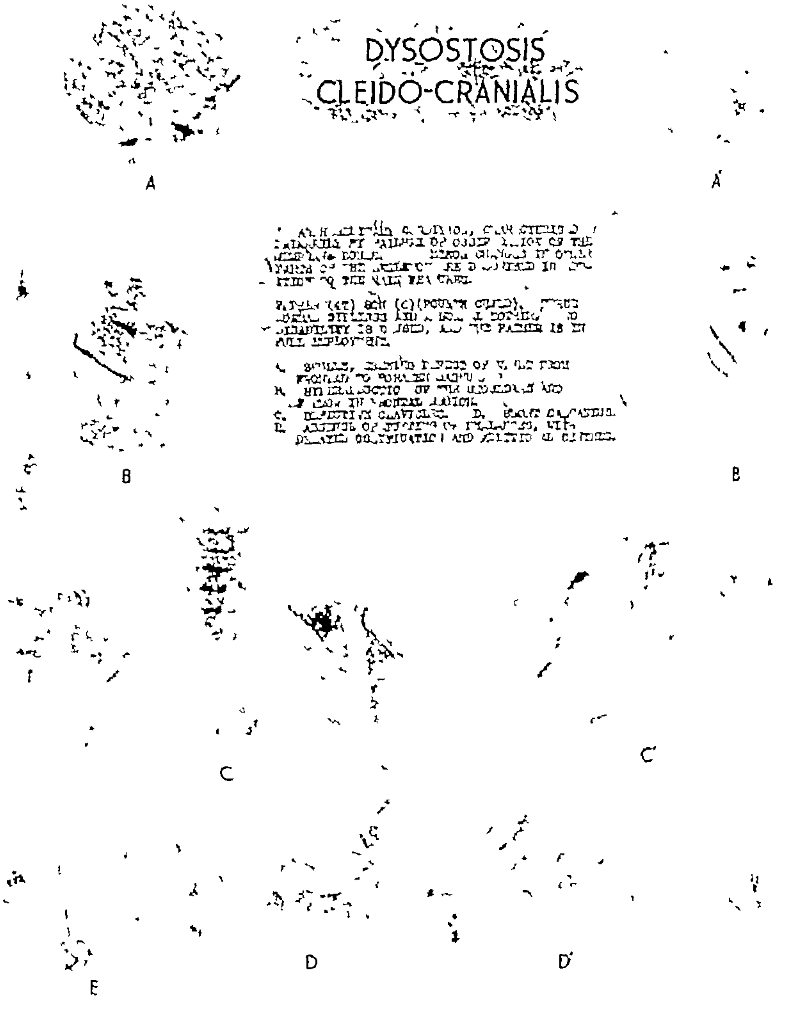

Fig. 4—A typical library card.

The new club for those in training.

QUARTERS

hile taking the course members live in a clubhouse the estate. Victorian stables have been converted quarters which have the atmosphere of a college er than a training centre. Financed by British indus- and by generous donations from various American ls—including the Rockefeller, the Vesey, and the mmonwealth Funds—and some American business s, this building is a harmonious background for free ussion in the evenings and at odd moments. Since y of the furnishings come from America it has ped the air of austerity investing most British erprises nowadays.

he aim of the courses at Roffey Park is to bring to life material collected laboriously into Government and er reports—*notably those of the Industrial Health* earch Board—and too often forgotten before a year ut. This is a first attempt to disseminate the findings uch bodies among those who can use them practically, in fact to study and teach all of mental health in ustry. It deserves success.

INTERVERTEBRAL DISC SURGERY

Principles and Results

s a Hunterian lecture at the Royal College of Surgeons Oct. 17, Mr. MURRAY FALCONER said that the results operations on the intervertebral discs in the past e been inexplicably variable. Large prolapses may removed with an indifferent result, while great relief often followed a disappointing exploration. Surveys large series have always shown satisfactory results less than 75–80 % and often in as few as 50 % of cases. mpetent surgeons have recorded negative explorations as many as a fifth to a third of their cases, and in ny patients symptoms have persisted whatever the erative findings.

Mr. Falconer has analysed the first 100 consecutive erations performed at the neurosurgical unit established Otago in 1943. In every one of 77 patients with severe atica one or more prolapses were found, and all timately benefited, though 9 had to be operated on ain. In 23 with low back pain alone only 1 explora- n was negative, and all but 2 were relieved by operation. ctors governing the success or failure of disc operations d under the control of the surgeon include selection of ses, exposure, recognition and removal of the lesion, d management of convalescence. In selecting cases must be remembered that acute symptoms mostly ear up spontaneously—only 1 in 9 of these came to eration—and intervention is indicated only if four eeks' complete rest in bed leaves the patient unrelieved d unfit for light work, and if the radiogram excludes berculosis and neoplasm of the spine. Cases should ot be excluded because psychoneurotic features develop n a physical basis; many of these have done surprisingly ell. In patients with low back pain alone selection ust be much more cautious; only when, besides a rigid spine and intractable symptoms, there is a positive myelogram should exploration be performed.

Regarding surgical exposure, Mr. Falconer holds that the old interlaminar approach gave an inadequate peephole view which was often the cause of failure to detect the lesion. A full laminectomy, with removal of the 5th lumbar arch and the lower part of the 4th, was done in most of his cases and gave the best results, leaving no disability or incapacity for hard work. Recognition of the lesion demands acquaintance with the four main types of pathology. There is the simple protrusion, covered with a thinned annulus, and the extrusion through the annulus, often pedunculated. Then there is the important intermittent prolapse, equivalent to Dandy's "concealed disc," which looks normal, though it is soft to the probe and may not even bulge until the spine is hyperextended on the table; it is important to recognise and remove these, for they formed 20 % of the whole series. Finally there are the 5 % of scarred discs, greatly narrowed over the years and associated with osteophytic outgrowths on the adjacent vertebral borders. It is necessary to explore both the 4th and 5th spaces in all cases, and 27 patients had a double lesion. Thorough curettage is essential, for any loose material left in the interior of the disc may be extruded later through the operative gap in the annulus under the stress of weight-bearing. So curettage should be done from both sides of the theca whenever the prolapse extends towards or beyond the midline. Removal became more radical with experience in the Otago series, and it should include the cartilage plates so as to leave bare bone approximated. Cadaver experiments have shown that much more material can be removed by a bilateral approach, though this still leaves a blind angle directly in front of the theca. There is a real, though very small, risk of the curette emerging anteriorly and endangering the great vessels.

Spinal fusion is unnecessary, in Mr. Falconer's opinion. At first, in his operations for low back pain, his orthopædic colleagues fused alternate cases as a control; but this was soon abandoned because the grafts often broke or demonstrably failed to fuse to the sacrum, owing to the great stresses at this level, and the unfused cases had a smoother convalescence. It is important to begin exercises for the wasted erector-spinæ muscles at the eighth to tenth day; light work is resumed in two to four months and heavy work in four to six months.

From the aspect of differential diagnosis, the hypertrophied ligamentum flavum is merely the thickening of a relaxed ligament associated with a disc prolapse; it has never been seen without prolapse. Arachnoiditis and radiculitis are always secondary to the root compression. Cauda-equina tumours can be differentiated by myelography, and spinal tumours are usually sufficiently obvious; but a real, though rare, hazard is the small tuberculous focus encysted partly in the disc and partly in the adjacent vertebral body. In one such case death from miliary tuberculosis ensued after curettage.

Re-operation is called for whenever disabling symptoms persist or recur, and was done on 14 occasions. Such persistence or recurrence must indicate residual loose fragments whether they were missed at the first operation or have developed since, or have appeared at another level. A 100 % follow-up has shown results very similar to those generally reported with another mechanical, non-lethal, incapacitating skeletal disorder—internal derangement of the knee-joint. Good (60–75 %), fair (15–25 %), and poor (5–10 %) results were much the same in both. In both groups re-education of muscle is important and there may be late osteo-arthritis of the joint, though in the spine there is the added risk of pathological changes in another disc.

The essential points in disc surgery, Mr. Falconer summarised, are these. Adequate exposure usually calls for a laminectomy. The pathological appearances must be familiar, especially those of the intermittent prolapse. All readily detachable material must be removed, if need be from both sides. The erectores spinæ must be re-educated. Finally, there must be no hesitation to re-operate if disabling symptoms persist or recur.

are making the best use of their photographic units. Means of improvement are suggested. The subject as a whole has been divided into the following three main headings: (1) routine recording with (2) filing as the logical connecting link between records thus obtained and (3) the adaptation of records to education in medicine.

References to other work are given where it has been felt that insufficient information could be imparted in limited space, but there has been no attempt at a comprehensive bibliography. It is only through a complete understanding of the points mentioned, and to some extent of the processes involved, that imaginative use can be made of the photographic department. The hospital staff must coöperate freely, and in return they may expect high quality records and teaching material.

We wish to acknowledge with gratitude the assistance of Miss F. E. McAdoo, of Westminster Hospital; Mr. J. Kilshaw, of Manchester Royal Infirmary; and Mr. F. Wardlaw, of the Christie Hospital, Manchester.

BRITAIN'S CALORIE REQUIREMENTS

NUTRITION SOCIETY CONFERENCE

A CONFERENCE on British needs and resources in calories, proteins, and calcium was held in London on Oct. 25, with Mr. WALTER ELLIOT, F.R.C.P., F.R.S., in the chair.

In a paper on food requirements Mr. E. R. BRANSBY, PH.D., Dr. H. E. MAGEE, and their co-workers took as a basis standards suggested by the Technical Commission of the League of Nations in 1926 and 1938. The commission's reports, while suggesting a desirable level of protein intake, did not define the proportion which should be first-class; but the Mixed Committee of the League recommended that 50% should be of animal origin. Dr. Bransby held that the recommendations which had been made on the amount of animal protein to be included in the diet had not been supported by experimental evidence; his estimates of requirements were based on prevailing dietary habits. He and his associates have worked out how these requirements may be met from a diet composed of milk, meat, fish, bacon, offal, eggs, cheese, potatoes, vegetables, fruit, pulses, sugar, preserves, sweets, cereals, and fats. To bring the nutritional level of the British people up to that considered desirable in the light of the League's recommendations the following percentage increases on pre-war consumption would be needed:

	Increase %
Dairy products or milk solids	48
Sugar	14
Meat, fish, eggs	5
Potatoes	56
Vegetables	27
Fruit (as fresh fruit equivalent)	1
Grain	6
Fats	Nil

Prof. JOHN BEATTIE had found in Germany that men fed on a diet of 1750 calories lost weight for about four months, at the end of which they reached nitrogenous equilibrium, in which it seemed they would remain indefinitely. They could in fact be maintained in equilibrium on a daily intake of 35 calories and 0·5 g. of protein per kg. body-weight. Placed on forestry work they lost weight even though given an extra 500 calories a day; this was because most of the extra calories were used not for work but for raising the basal metabolic rate. Professor Beattie felt that if the population of Britain were reduced to a low nutritional level, a great deal of extra food would be needed when the attempt was made to bring it back to a proper working level because of the amount required for raising the metabolic rate.

Mr. E. C. OWEN, PH.D., suggested that Dr. Bransby had been liberal in recommending 1 g. of calcium per day. He himself had observed that in elderly men calcium balance could be maintained on an intake of per day, and in very old men on 0·29 g. per individual requirements varied widely. He that care should be exercised in estimating of animal protein in the light of recent had shown that glycine was present in but absent from many vegetable proteins.

TRAINING COURSES AT ROFFEY

THE work of Roffey Park Rehabilitation already been reviewed in our columns.[1] under the direction of Dr. T. M. Ling, provides and reablement, in very good surroundings, for who break down, or prove unequal to their result of industrial fatigue, depression, nervous or other occupational and psychological Patients usually stay some six or seven attractive country house, set in beautiful wooded during that time they are studied physically and logically, are helped to find congenial occupat various workshops, are built up physically by a class diet and by physical training in the and enjoy rest and recreation as well as pleasant life. The centre is largely supported by industry, maintains direct contact with 180 leading firms as with the health services. It has now been runn nearly three years, and results of a follow-up show some 82% of those who come for reablement settled back into work without further difficulty.

A NEW SCHEME

A training and research department has now established at the centre, the aim being to material provided by the patients who pass and to spread a better understanding of them, the science of human relations, among doctors, managers, personnel managers and other officials, trade-union officials, and social w hospitals. Roffey Park can accommodate patients at a time; so more than 1000 pass th yearly, all of whom are suffering from ind ill health, often the result of psychological ment. They thus offer wide opportunities for st

Training courses last a fortnight, and the falls under two heads: (1) maintenance of fitne work; and (2) special problems of reablement resettlement. The members—who are drawn from the classes mentioned above—attend lectures and cussions, see films and filmstrips, study case-his and have appropriate cases demonstrated to Plenty of time is allowed for free discussion among members, for they have much to teach each other often much to learn. Members with special expe are asked to give talks on their own subjects.

In the current course, for example, a member tal "Training Within Industry" (T.W.I.) which many firms are now introducing. The first step, he explai the training of trainers; and he discussed in outline the of course which supervisors—whether they are or charge-hands—need to take. They must, he familiar with the work and with responsibility, and be skilled in instructing, in improving methods, and in Each supervisor must prepare the worker for the new demonstrate the operation, watch him try the and follow his progress. To improve training methods, must know how to "break down" the job, so that consider it at every stage. These common-sense prin however, are not always easy to apply in the rush of day's work; and in the keen discussion which followed talk it became clear that supervisors sometimes slip and also that some managements pay lip-service to without giving it real support. Yet a good adjustment new job depends greatly on good preparation for it; bad start may be the making of a "misfit."

The team conducting the course consists of Dr. R. Tredgold, psychiatrist; Mr. Jerome F. Scott, an Ame industrial sociologist who trained at Harvard under Elton Mayo; and Miss J. Kirby, the social worker to the centre.

---

Letters to the Editor

ICILLIN AND INFECTIONS OF THE FINGER

R,—I was interested that Dr. Webster (Oct. 25) treated paronychias by infiltrating the nail-fold with cillin solution but had found the treatment an mfortable one for the patient. Nevertheless an riment of this kind would be well worth while if, e not being too painful, it could obviate the necessity removal of part or all of the nail, as is so often mmended. The pulp of the finger has lost much of sefulness to a manual worker if the strong support counter-pressure afforded by the nail is removed.

here in these chronic paronychias pus is discharging the sulcus between fold and nail, an effective treat- is to instil gently a few drops of penicillin solution this sulcus. A hypodermic needle from which the has been filed is a useful means of doing this. sulcus is surprisingly deep in these cases, and if a patience is exercised it is possible to slide the needle down and perform the instillation with no discomfort. But the nail-fold itself is not infiltrated. or two treatments are often quite sufficient to cure, ially if an adhesive waterproof dressing is applied ediately after the treatment.

lo not think that the hospital treatment of late cases systemic penicillin reflects the great advance that treatment has bestowed upon the early case. My strial experience is that more cases resolve than before without suppuration; but the chief benefit at further spread of infection is discouraged. The hylococcus would seem to produce necrosis very kly, so that an "early" septic finger may already a slough in the tissues by the time that treatment arted. In fact the clinical appearance of an early n is possibly as much due to reaction to slough as to ion to infection. But in industry one can catch so early that this necrosis should be minimal.

ford. G. WHITWELL.

BUSE OF THE EMERGENCY BED SERVICE

R,—Nobody cavils at Dr. Herbert (Oct. 11) ing a suspected case of appendicitis to hospital. surely it is helpful both to the patient and to the eon, who has to make the final decision, to transmit ossible information about the case. It would have n but a few minutes to note the time of onset and ite of the pain, and the temperature, together with abdominal and rectal findings. Since the patient not arrive at hospital until "several hours later," value of such a record would have been so much greater.

remember a patient I admitted once for an outside or. He arrived one Sunday afternoon while I was ged on an accident case and was sent straight up he ward. Half an hour later he was dead from emia. The doctor's laconic note said: "Septic d for two days—requires hospital treatment." For pleasantry I had to answer in the coroner's court.

Dr. Herbert wonder, therefore, that Dr. Kagan ld have reached the conclusions he gave in his letter Oct. 4?

t the same time I should like to remark on the y feud that appears to exist between some general titioners and casualty officers. Even one of your patetic correspondents vented his spleen along these s recently. Casualty officers are not appointed for sole purpose of vexing their seniors in general ctice. Even with the help of nurses and almoners are as busy as, if not busier than, the average eral practitioner. Westminster Hospital is one of smaller London teaching hospitals; but I recall t, when I was R.M.O. there, two other casualty officers myself saw between 3000 and 7000 patients a month, ording to the season of year. Those are figures for ual attendances—not possible attendances from a el list. Of these, a higher proportion needed admission n in general practice. Casualty officers often have ater difficulty than G.P.'s in finding a bed for a patient, many a time have my colleagues and I been pro- ndly thankful for the services of those courteous ies of the E.B.S.

We "omniscient juniors" are fully aware of our shortcomings and realise that we can learn only by experience and the example of others. But what can we learn from a case of "appendicular colic" sent "for observation and, if necessary, surgery" with an illegible note describing it as "acute appendicitis" but without reference to a single relevant clinical finding? We might do much worse than "wag a finger"—we might imitate.

London, S.W.17. CHARLES M. FLOOD.

ORIGIN OF CEREBRAL SURGERY

SIR,—As a student at King's College Hospital in the earlier '80s I was present when Sir Joseph Lister, as he then was, operated on a case of cerebral tumour. I can see now Ferrier (for whom I "clerked") proceeding to indicate the position of the tumour in the left parietal region, and the restraining hand of Lister preventing actual contact with the patient.

As to the precise date I cannot certify, but doubtless the surgical registrar at King's College Hospital could establish the priority or otherwise of Rickman Godlee's operation. We understood at the time that it was the first operation of the kind.

Farnborough. M. P. HOLT.

SECOND ATTACKS OF POLIOMYELITIS

SIR,—The interesting letter from Colonel F. M. Lipscomb and the annotation in your issue of Oct. 11 prompt me to record briefly a further case, which is at present under my care.

The patient, a boy aged 9, was admitted to the Kingston County Hospital on Sept. 23 with a history of headache, vomiting, neck stiffness, photophobia, and general malaise for the past two days. The boy had had a definite attack of poliomyelitis in September, 1946, with involvement of muscles in the left arm and right leg, and residual weakness in the left deltoid and right anterior tibial muscles. On admission: temperature 100·2°F, pulse-rate 112 per min., respiratory rate 23 per min. The cerebrospinal fluid showed normal pressure and contained 69 cells per c.mm., all lymphocytes, and 30 mg. protein per 100 ml.; the Wassermann reaction was negative. Three days later the boy developed marked weakness of the muscles of the right forearm and hand—muscles which were not affected at any time in the previous attack of poliomyelitis. The pyrexia persisted for about seven days, but the temperature has since been normal.

This is a case in which a second attack of poliomyelitis has come on just over one year after the first attack.

Kingston County Hospital,
Kingston-on-Thames. A. A. CUNNINGHAM.

COAGULATION FACTORS

SIR,—My associates and I consider your leading article on Sept. 13 to be misleading and inaccurate.

Rhoads and Panzer,[1] not Quick, were the first to show that the prothrombin-time steadily increased as plasma storage was prolonged. This was cautiously interpreted to mean a decrease in prothrombin concentration. Quick[2] confirmed the erroneous interpretation. Those who used the more reliable two-stage method for measuring prothrombin activity found prothrombin to be relatively stable in blood-bank blood.[3] Quick abandoned his view which held that prothrombin disappears in blood-bank blood. He postulated that there are two prothrombins and that one of these disappears in storage plasma.[4]

Meanwhile isolation work on prothrombin described by Seegers, Loomis, and Vandenbelt[5] showed that Quick's theory could not be correct because their work showed no evidence for a second prothrombin. They stated: "It, therefore, seems to us that his experiments will eventually be reinterpreted." In his many subsequent communications Quick failed to cite the work of

In England Now

A Running Commentary by Peripatetic Correspondents

MUCH has been written about the hazards of an assistant's life in general practice, but worst of all are the appalling vehicles with which one is expected to perform one's duties. At the end of one of my earliest locums for an irascible Irishman he inquired how I was getting on with his "so-and-so patients." "All right," I replied, "but not so well with your so-and-so car." (It was 17 years old and had been driven hard.) "Faith, an' it *is* a so-and-so car," he muttered complacently setting off for the pub in his new Lagonda. Once I had to greet him on his return from a holiday with the news that owing to my tardy diagnosis one of his pet private patients was very ill with diphtheria. He patted me consolingly on the back, saying "Never mind, my dear, we all make mistakes. Now when I was a young doctor I remember. . . ." His voice trailed away and then suddenly hardened as he caught sight of a minute dent on the mudguard of his 80,000-mile Standard. In an altered tone, he said "Really, Doctor, I think you might have been more careful with my car."

The new graduate about to take an assistantship "with car provided" should not be put off with the statement, "It has just had a new engine." There are plenty of things besides the engine which can go wrong, as you'll find out. Beware of the employer who tells you, "There's nothing radically wrong with this car." There must be, or he wouldn't need to mention it. Always put the leading question, "How does it start in the mornings." If the answer is "Oh, very well, if you leave it on a hill," look out for another job or buy your own car.

I will end with a story which contains a warning for all mothers about to undertake general practice. The boss was talking about the difficulties of getting an adequate diet for the nursing mother. "I take off my hat," he remarked, "to any woman who can breast-feed a baby on present-day rations." I reminded him that I had breast-fed three in the last four years and awaited a murmur of admiration. It came, but in an unexpected form. "Why, you must be as strong as a horse, doctor." And after a pause, "You won't mind starting the car with the handle in the morning; it would be expensive to get the self-starter repaired."

* * *

The day after I was demobbed I went through my old trunk to get rid of the accumulated junk, and a charming letter from Leading-seaman B reminded me of that day in June, 1944.

It was about 10 days after D-day, off the Normandy coast, and the ship was rolling and pitching when I was called to the sick-bay to see B who presented typical early symptoms of acute appendicitis. I put him to bed and then asked the Old Man how soon we could get him ashore—but not a hope. We were Senior Officer of a group of frigates (how annoyed I used to get when people asked me how many sails a frigate had!), and we had to remain on patrol. I then read up appendicitis and examined the patient again and became even more worried as I decided it was retrocæcal.

I surveyed my equipment—or lack of it—and made plans. No steriliser, no sterile gowns, &c.; so I sent for the Chief P.O. cook and we wrapped some gowns and sheets in canvas and put them in his oven, and I commandeered his steamer for instruments, gloves, and swabs. Returning to the sick-bay I was just in time to save the patient from being castrated by a shaky S.B.A. who was trying to "prep" him with a fiendish-looking knife. How easy it would all have been in hospital, I thought. Just a few words on the phone and all this is done—ready for the surgeon's arrival. It would do some surgeons good to do the preparations for their own operations once in a while.

After some argument, I persuaded the First Lieutenant to be anæsthetist and a couple of subbies to be "dirty nurses"; the S.B.A. would assist. The Old Man slowed to 9 knots, and put her bows into it, and I, having read up appendicitis for the tenth time, started the anæsthetic at 2300 with the patient strapped to the table. The patient "under" I scrubbed up, picked up the scalpel, and made the incision—right paramedian—much annoyance of the patient, who was quite Number one had decided that I had given too ether and thought that one drop a minute was having persuaded him to be more liberal, I started

Things proceeded nicely until one of the fainted, and later when I was reaching for a Wells the other subby put his dirty fist into the and gracefully presented me with one. I only had so I had to use it.

The appendix *was* retrocæcal and the very to get out, but wasn't I pleased when I saw horribly pathological thing it was? I popped it spirit afterwards and kept it.

I was just finishing the purse-string when a came from the Old Man with a warning that we altering course and speed; a moment later " Stations" rang. Away dashed my anæsthetist dirty nurses, leaving the S.B.A., the patient, and As we swayed and reeled, I managed to stitch up the ship did a depth-charge attack. Eventually finished, and for good measure I fixed up a saline drip with the bottle tied to the deck-head my braces. Three days later we landed our Falmouth and a fortnight after that he went on leave.

I never told anybody that it was my first app cectomy. After qualifying I'd done H.P. only for months. But I thanked my lucky stars for that stud H.S. I did before qualifying. I had at any rate often enough.

* * *

No doubt, Mr. Editor, you imagine that, as soon your journal arrives, we readers turn avidly to leading articles and gratefully imbibe your latest on the political crisis or on some new and discovery. You may find it hard to credit that is so misguided as to begin with the correspondence. As a man of method, this is, I my custom. But, unlike the weaker brethren, I add that I do not stop there. My second port of is Letters to the Editor—sometimes made less by my inability to remember what was said last Thence I turn back to the annotations and so to leaders, which (now that I am old) I read with in Duly strengthened, I go back yet further to the Orig Articles, finishing, contrarily, with the first, and no days skipping the gynæcological and surgical o unless a new operation on the prostate is describ Finally—you will never forgive this, Sir—I proceed tear out the articles which concern me. (I am af it is too much to hope for, but I do wish you would put two articles on different medical or patholog subjects on successive pages; it makes the filing difficult.) If an article is lucky it goes at once into appropriate folder, or into a lecture folder for car re-reading when next I am to talk on its subject; oth wise it goes into a drawer to wait until I have the time distribute the pages in my filing cabinet. (My draw is very full.) The rest goes into the wastepaper basket and if I am not too busy, or on holiday, the whole *La* is thus disposed of by Monday night.

I just thought you might like to know.

* * *

He said he had bronchitis; but when he had take off his turban and voluminous garabeya all I found wa that he had my mosquito-net and sheets as a fine set of underclothing. What is the medical etiquette in such a situation? I felt I must observe the secrecy that is the right of every patient. After all, he only revealed my property en passant, on his way down to his chest. I wistfully snipped my name from his vest and sent him back to duty—for he had nothing (else) the matter with him. Why should I give him both a holiday and the finest linen combinations in the Sudan?

* * *

The discovery of a new clinical phenomenon is a sufficiently rare event to be worth recording.

In the history of a patient newly admitted to hospital I read that he had noticed that his urine had turned green. I observed to my house-physician that he had no doubt been taking backache pills containing methylene-blue, but was informed that the patient had hæmaturia and was colour-blind.

MEDICAL JOURNALS FOR GERMANY

ir,—We frequently receive appeals from German tors for copies of The Lancet and other medical rnals. They know that in many fields advances re been made since 1939, but since then foreign medical iodicals have been practically unobtainable.

May I appeal to your readers to send any issues of e Lancet (or other journals) which they do not require doctors in Germany? We shall be glad to receive them this office, or would send the name and address of octor or hospital on hearing from interested readers.

A DESCRIPTIVE ATLAS OF RADIOGRAPHS

ir.—Your review of May 17, in quoting my remark at "vociferous radiologists who wish to keep radiology a closed art, a mystic rite," omits to mention that I cribed them as a "fortunately dwindling number." he radiographs in my descriptive atlas are as poor as e reviewer suggests, it is indeed brave of him to doubt accuracy of the diagnosis, which in most instances s made by the clinician in charge of the case. I mit that many of the figures, especially in the bone tion, are old. During the last twenty years treatment has advanced so much that what were once common eases are now almost museum pieces—e.g., rickets, philis, osteomalacia, osteomyelitis, varicose-ulcer nges in bone, and Ewing's tumour.

Parliament

FROM THE PRESS GALLERY

Debate on the Address

n the House of Commons on Oct 21, in moving that humble Address be presented to the King thanking n for the Gracious Speech from the Throne at the ening of the new session, Mr. W. R. Blyton welcomed e proposals made in it for ending the poor-law. That t, which originated in the reign of Queen Elizabeth, d been revised and amended many times, but the sic principle had always been that poverty was a crime. ople had shunned receiving assistance under the or-law and he was pleased to be able to play some part burying the Act. Miss M. Herbison, who seconded e Address, welcomed the Government's continued pport of the United Nations Organisation, and of the n of the Food and Agriculture Organisation to give adequate diet to every person in the world no matter at might be his race, creed, or colour. We must e to it, she added, that Sir John Boyd Orr's fears at this organisation would merely be a collector of tistics and data were not realised.

Mr. C. Attlee, the Prime Minister, said the Govern- ent's legislative programme for the coming session mpleted a system of social security by the abolition the remnants of the poor-law. Another important easure which the Minister of Health would introduce alt with the reform of the block-grant system. This uld be of great assistance to necessitous local thorities.

Sir H. Morris-Jones questioned whether we could aintain a population of 47 million people in this country the standard of life which we used to have in the old ys, and in particular he doubted whether the insurance islation passed last session could be brought into eration on July 1 next. In regard to the health rvices alone it seemed to him completely impossible view of the lack of accommodation in hospitals, the ck of medical and nursing personnel, and the lack of uipment to bring into force the scheme which was pposed to guarantee to every individual, man, woman, d child, in this country expert medical attention, rsing, dental services, and so on. If the Govern- ent were not in a position to bring these things about, would be very much better for them to be quite frank th the people and say so.

Mr. R. A. Butler, speaking for the Opposition, said at the proposal to reform the poor-law entailed the completion of social security work undertaken by the Coalition Government. The real threat to the social services came from the maladministration of the Socialist Party. If the Chancellor of the Exchequer should decide to reduce the range of the food subsidies the Conservative Party would be in favour of considering the interests of the most needy sections of the population in view of the heavy rise in the cost of living which would result.

Sir Stafford Cripps, Minister for Economic Affairs, said we must take steps to prevent the large adverse balance in dollars being realised. There was an ever-present danger that continued difficulties, and the lack of food and raw materials with its consequent tragic lowering of the living standards, might lead people, as had been seen in Germany after the first world war, to adopt methods and follow political creeds which were destructive of democracy and which accentuated those dangers of war against which we believed that a true democracy provided the greatest safeguard.

It was on our own efforts, said Sir Stafford, that we intended primarily to rely, and the most effective way of saving dollars was by the production of more food in this country. Food was the largest single item among our present dollar purchases and any food that we could grow ourselves would save dollars. But there must also be some immediate further reduction of dollar expenditure on food, which, if not replaced from elsewhere, would—with other changes brought about for quite other reasons—reduce our standard to just below 2700 calories a day, which, though highly unpleasant, should certainly not be disastrous. That would enable us to save about £66 million a year in dollars. In making these adjustments in our imports, the Government had to take into account the fact that the country had suffered the grave misfortune of a bad potato harvest. They must take strict measures to see that supplies lasted till the next crop was available. The saving would entail the following reductions in our food:

Sugar would revert to 8 oz. a week from the 10 oz. to which it was recently raised: meat would remain at 1s. a week: bacon would remain at 1 oz. a week, and there would be a saving on eggs which would enable a distribution to be made of 66 shell eggs compared with 58 last year, with an earlier exhaustion of dried egg stocks.

If circumstances improved, he added, or if matters were eased for Europe and the world by the adoption of some scheme under the Marshall Plan, then the British Government could always reconsider the matter, and, if necessary, increase our imports again. But he was convinced that it was necessary to take this step of further adjusting our consumptions and imports forthwith.

Mr. H. Dalton, Chancellor of the Exchequer, announced that the National Insurance Act and the National Health Act, both passed last session, would come into operation in July and would not be delayed. Taking account of the transfer of hospitals from local to national funds, the ending of the poor-law, and the new block-grant, there would be a substantial reduction of the rates in many parts of the country, and particularly in the poorer industrial and rural areas. This would be a valuable measure for laying a foundation for the recovery of industry.

QUESTION TIME

Meetings of the Negotiating Committee

Sir E. Graham-Little asked the Minister of Health how many times he had personally met the Negotiating Committee appointed with the approval of the Minister by the medical profession, to discuss regulations to be made under the National Health Service Act: and what was the date of the last such meeting.—Mr. A. Bevan: These discussions have so far taken place with my officials following a procedure which I believe to be entirely acceptable to the Negotiating Committee. At their request I have arranged to meet the committee myself next month.

Working Party on Nursing

Mr. G. R. Mitchison asked the Minister whether he had any statement to make on the report of the Working Party on the recruitment and training of nurses.—Mr. Bevan: The Secretary of State for Scotland and I have promised to consider the views of the nursing organisations and other

Seegers, Loomis, and Vandenbelt. Fantl and Nance [6] confirmed the conclusion of Seegers, Loomis, and Vandenbelt and not, as you state, the work of Quick. Fantl and Nance also showed that an accelerator factor increases the activation rate of prothrombin. This observation has been confirmed by Owren [7] and by Ware, Guest, and Seegers.[8] The fact that prothrombin-conversion rate is profoundly affected by the plasma was repeatedly referred to by Smith and his associates,[9] and in one communication Smith stated: "Recent work indicates that the rate may also be determined by a 'convertibility factor' of unknown nature."[10]

In 1946 Quick [11] abandoned the theory of two prothrombins, and referred to the old prothrombin A as "component A." This component A now becomes the labile factor.[12] In another communication Quick [13] presumes that component A is identical with the accelerator factor of Owren. The accelerator factor would then need to be labile. Owren reports that 60–70% of the accelerator factor remains at the end of one week of storage. The question is whether Quick would adjudge that to qualify the accelerator as a labile factor. Our own work with bovine plasma shows that the accelerator is stable and can be isolated after 18 days' storage.[14]

From all this work we can now conclude with certainty that only one prothrombin exists and that a factor accelerates the interaction of prothrombin and thromboplastin. The account given above records who established these facts.

WALTER H. SEEGERS.

Wayne University, Detroit, Michigan.

PRIVATE WARDS IN HOLLAND

SIR,—The concluding sentence of my previous letter (Oct. 4) did not make my point clear enough.

Your correspondent in his article on Sept. 6 (p. 363) expressed the view that if private wards or private rooms for patients who pay higher rates are incorporated in hospitals with ordinary wards, these private wards and rooms should not be brought together in separate blocks or units but should be distributed over the units with ordinary wards.

Our experience in Holland (where there is a strong feeling against nursing-homes and where for a number of years very many hospitals have had combined ordinary and private wards) is that combining private and ordinary wards in one nursing unit makes for difficulty in nursing and administration and provokes jealousy among patients in ordinary wards, due to different visiting hours. Our experience shows that the separation of ordinary wards from private wards does not interfere with the achievement of the same standard of nursing and care in both units; and it does not mean that in the same hospital the one department is better managed than the other.

Deaconess Hospital, Meppel, The Netherlands.

J. C. J. BURKENS
Medical Director.

THYROID AND LACTATION

SIR,—I should like to comment on Dr. Margaret Robinson's article in your issue of Sept. 13.

Table II gives the mean daily output of breast-milk for each group of 20 mothers, but not the variance of the individual figures; this makes it impossible to apply the precise *t*-test for the significance of the variations between the means. The absence of the detailed data also makes it impossible to work out a correlation coefficient for the effect of thyroid on breast-milk; calculation of the coefficient for the means as given suggests that the effect, though definite, is but slight. There is obviously no correlation between milk and the dose of thyroxine (table III).

Is it not possible that these huge doses of thyroid have spilled over into the breast-milk, stimulat nursling to suckle more vigorously, and so i the milk-flow? And is Dr. Robinson satisfied lactation is established, when the daily output a month is 13–14 ounces (the average of the figures) doubt if the month-old baby would be. I consider her interesting experiment does not warrant her conclusion; it would be more accurate to say thyroid produces a variable and inconstant in the milk-flow, and to leave it at that.

London, N.W.3.

E. H

THE NEW ZEALAND SCENE

SIR,—Further advices from New Zealand reveal all the schemes for the (partial) general- service which have been essayed from time t during the past eight or ten years are now in the A new committee is to be established to review the situation afresh, and it is perhaps significant t minister of health who held this office throughout period in question has now been replaced. The with the past seems to be complete.

A letter in the *Daily Telegraph* of Oct. 1 from a in New Zealand fully supports the statements I my letter of Sept. 20 to you (p. 452). I have further communication, dated Sept. 30, from a in the R.N.Z.M.C. who also confirms those st He adds that "no young doctors will join the R.N.Z for service in Japan" (where he is now stationed) the prospects of general practice are too attractive, their seven and sixpences ad infinitum for even the junior man," and in consequence of the absence of teers from New Zealand it has been decided to further medical replacements for this corps in

House of Commons.

E. GRAHAM-L

MANGANESE TREATMENT OF BOILS

SIR,—There seems to be a growing tendency, with almost daily introduction of new treatments, to older and well-proved methods. For many have found the best, easiest, and most econo treatment of furunculosis and allied staphyloco conditions to be manganese. During more than years' service in the Royal Air Force large number men and women came under my care, including, of co many cases of staphylococcal infections and furuncul especially among the younger and adolescent gro The important thing was to keep as many as po on the job while still undergoing treatment. No atte at a controlled trial was made, but the treatment choice was agreed to be colloidal manganese, except in rare acute cases where admission to hospital for penici treatment was resorted to.

Dosage varied according to the predilection of diffe medical officers, but in my own experience a course of injections of 1 ml. at three-day intervals was the successful and produced no toxic effects. The in was given intramuscularly into the upper deltoid, muscle well massaged, and the patient told to use arm as much as possible. It was rarely necessary a second course of treatment to be given, and I do remember a third course being embarked on, with the constant movement of personnel this have happened without my knowledge.

Colloidal manganese is easily stored, easily and economical; change of temperature does affect its efficacy, and its non-viscous nature allows ordinary hypodermic needle to be used for the inject

There is no precise rationale for the use of man therapy in staphylococcal infections, though, since metal plays an essential rôle in certain enzyme syst it seems possible that it acts by interfering with nutrition of bacteria by some mechanism not unlike of sulphonamides. But the proof of the pudding is the eating, and I should be sorry to see this form of ment disappear from the armoury of the gen practitioner.

Sheffield.

ch joined the staff of the hospital my admiration clinical wisdom, for his humanist outlook, and for ady and complete command he always showed over h clinical experience, never ceased to grow.

was singularly good company; his dry humour ned his conversation, and made those too brief eeting contacts, snatched from busy professional that his friends made with him, delightful oases which they returned, refreshed, to work again. s his contemporaries, therefore, something precious ave departed from the hospital community in which we shared, and from that body of recollections make up so much of the satisfactions of life as aw towards its later years. To leave such a sense s is perhaps the last and truest test of a man's

F. M. R. W.

those many neurologists who benefited from dier Riddoch's guiding hand during the war years, dden death must be felt as a great personal loss. nsulting neurologist to the Army he acted as a link in the application of the knowledge gained in 18 to the problems presented in the second world while his additional consultant appointments to .M.S. and Ministry of Pensions enabled him to ate the military and civilian effort.

development of centres for the treatment of ds of the brain, spine, and peripheral nerves proved an essential part of the medical war effort, but the Dr. Riddoch played in insisting on the need for centres and in guiding their development may have me extent been forgotten. His tireless round of to these special centres was of great value in oping the remarkably high standard of treatment was achieved, and this has often been acknowd by the surgeons in charge of these special units. ept a watching eye on all the neurological and surgical services in this country, and with Sir Hugh s planned the staffing and placing of neurological overseas. Those of us who played a part in this isation, however humble, always felt grateful to der Dr. Riddoch's considerate and friendly direction. ite of indifferent health during the latter part of the his energy and enthusiasm never flagged, but the of work and travelling under war-time conditions have contributed to his illness. After an operahe insisted on returning to duty within a few weeks. he continued in uniform until the end of the war. orge Riddoch was known throughout the world as of Britain's leading neurologists, and his self-sacrificdevotion to duty during the war years was an ration to us all.

W. R. R.

. Riddoch married in 1916 Margaret, daughter of the late Ledingham of Aberdeen. They had a daughter and two , one of whom is a member of the medical profession.

Appointments

r, W. H.-P., M.D. Lond., M.R.C.P.: physician to outpatients, The Children's Hospital, Birmingham.

MER, M. H., M.B. Camb., F.R.C.S.: surgical registrar, The Royal Cancer Hospital (Free), London.

NSTON, J. O., M.B. Belf.: asst. county M.O.H. and M.O.H., Docking, Walsingham, and Wells.

TIN, J. J. B., M.D. Edin., F.R.C.P.E., D.P.M.: senior asst. physician, St. James Hospital, Portsmouth.

don County Council Mental Health Service:

RAUPL, FRITZ, M.D. Prague, D.P.M.: senior registrar, Maudsley Hospital.

MACDONALD, C. K., M.B. Edin., D.P.H.: asst. pathologist, Epsom Pathological Laboratory.

OST, FELIX, M.B. Lond., M.R.C.P., D.P.M.: asst. physician, Maudsley Hospital.

LEY, J. H., M.B. Lond.: senior registrar, Maudsley Hospital.

don County Council School Health Service:

RIMALDI, C. B., B.M. Oxfd: asst. M.O.

EUSTATTER, W. L., B SC., M.D. Lond., M.R.C.P.. consultant psychiatrist.

onial Service:

BLACKABY, E. J., O.B.E., M.R.C.S., D.T.M. & H.: senior M.O., Uganda.

HILLARY, BRIGID, M.B. N.U.I.: lady M.O., Malaya.

LITTLEJOHN, JOHN, L.R.C.P.E.: M.O., Kenya.

O'DWYER, J. J., M.B. N.U.I.: M.O., Nigeria.

THOMSON, G. M., M.C., M.D. Edin., M.R.C.P., D.P.H.: adviser on venereal disease control, West Indies.

Public Health

Disinfestation by Municipal Authorities

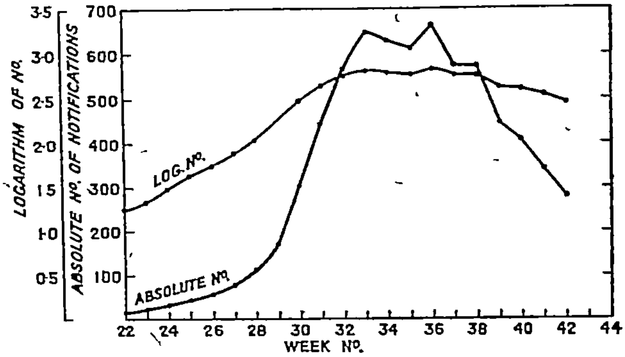
A DISINFESTATION service provided by the Salford health department has proved its value over the last three years. It comprises two men, a motor-van, and spraying and dusting equipment.

The demand has been sufficiently strong for the service to pay its way; nearly a thousand jobs are done each year. The corporation housing department, landlords, and the general public seem nowadays to be more willing to have premises disinfested, and moreover to pay for this; and workers in school and factory canteens are eager to see that the premises in which they work are reasonably fly-free. With new remedies such as D.D.T. and gammexane, and simple methods of application, the cost is low. In Salford typical charges are of the order of 21*s.* for eradication of bugs in a dwelling-house, 5–15*s.* for eradication of cockroaches, and 12*s.* 6*d.* for fly-proofing of a canteen kitchen.

A solution of 3% D.D.T. in kerosene has been found a useful insecticide against the bed-bug and house-fly; one application has proved sufficient for complete eradication of bed-bugs. Running insects appear to be more susceptible to D.D.T. in dust form; but in the case of cockroaches more than one application is often needed. Two treatments at an interval of three months maintain premises reasonably fly-free throughout the summer.

Poliomyelitis and Polioencephalitis

Notifications of poliomyelitis in England and Wales in the week ended Oct. 18 fell to 276, a reduction of about 18% on the figure for the previous week (338). The decline has now been established for six weeks. There was no obvious difference in the decline registered in different parts of the country, but it was perhaps more noticeable in the South than in the Midlands and North.



The Third Quarter

The Registrar-General [1] reports that 216,310 live births were registered in England and Wales in the third quarter of this year—18,727 fewer than in the second quarter. The birth-rate of 20·0 per 1000 population reflects the continued decline in the rate, which, having risen steadily since the end of the war to a peak of 22·8 in the first quarter of this year, began to fall in the second quarter when it was 22·0. It may be compared, however, with an average rate of 15·7 for the September quarters of the five years 1941–45. Stillbirths registered in the quarter numbered 5024, giving a rate of 22·7 per 1000 total births or 0·46 per 1000 population, compared with 26·6 or 0·53 in the September quarter of last year.

There were 97,066 deaths, the death-rate of 9·0 being 0·3 below that of the corresponding period a year ago.

Infectious Disease in England and Wales

WEEK ENDED OCT. 18

Notifications.—Smallpox, 0; scarlet fever, 1352; whooping-cough, 1009; diphtheria, 202; paratyphoid, interested bodies before policy is finally formulated and these views are now being obtained. The Working Party's recommendations concern, however, long-term policy and cannot be expected to produce an immediate increase in the supply of nurses. We trust hospital authorities will, therefore, at once examine interim measures to reduce wastage and will make the maximum use of part-time and married nurses and build up their domestic staffs to relieve nurses of domestic duties.

---

Obituary

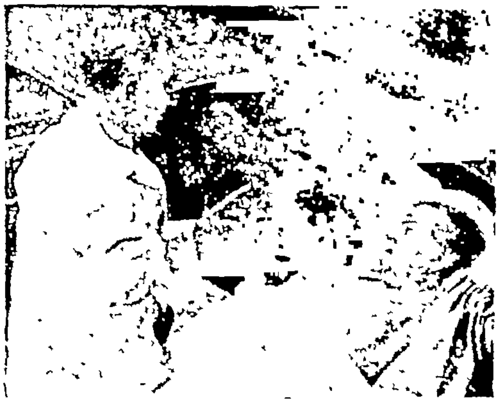
GEORGE RIDDOCH

M.D. ABERD., F.R.C.P.

At the age of 58 Dr. Riddoch died in the London Hospital on Oct. 24 after an operation. He was a distinguished neurologist and an able teacher: but his pupils and his patients will think of him first as a person and a friend—a man of singular kindness and a good doctor. Much of what he taught is remembered because he said it, and because of the way he said it; and through his teaching at the London and the National Hospital, Queen Square, he did a great deal to improve standards of practice. To his work at these two hospitals and in two wars the following appreciations pay tribute.

* * *

George Riddoch was born at Keith in Banffshire. After a distinguished career as a student he qualified at Aberdeen University and came to London just before the 1914 war. He obtained his introduction to neurology as a resident at the West End Hospital for Nervous Diseases. During the 1914 war he served in the R.A.M.C. as medical officer in charge of the Empire Hospital for injuries of the nervous system, and this brought him into contact with Henry Head who at once recognised his outstanding ability. Riddoch was already well trained in anatomy, having been demonstrator in the anatomy department at Aberdeen. His association with Head launched him into the main stream of the British tradition of neurology, springing from Ferrier and Hughlings Jackson, with its dynamic approach to the subject and its intimate relationship with neurophysiology.



During the years immediately before 1914 Head, with various collaborators, had been working on problems connected with sensation at all levels of the nervous system, and not many years previously Sherrington had published *The Integrative Action of the Nervous System* which had so greatly illuminated the reflex functions of the spinal cord. The time was ripe, therefore, for the application of these new ideas to the interpretation of the rich clinical material provided by war injuries, particularly of the spinal cord. Encouraged by Head, Riddoch in 1917 published papers on "the reflex functions of the completely divided spinal cord in man compared with those associated with less severe lesions," and in the same year, in collaboration with Head, he wrote on visual perception after occipital injuries and on "the automatic bladder, excessive sweating, and some other reflex conditions in gross injuries of the spinal cord." Though opinions are still divided as to the nature of the "mass reflex" and the interpretation of some of the reflex phenomena described, his work was a valuable contribution physiological interpretation of human nervous and this remained his approach in his later publ of which the chief were his Lumleian lectures to Royal College of Physicians, on pain of central and his presidential address to the neurological of the Royal Society of Medicine, on phantom limb body shape.

The end of the war saw him at the age of 30 established reputation as a neurologist. He r the need for enlarging his clinical experience and t the Medical Research Council joined the staff of the founded medical unit at the London Hospital, shortly afterwards he became assistant physician to Hospital for Epilepsy and Paralysis, Maida Vale. now shows that he possessed the powers of analysis and lucid exposition of a first-rate even though at that time his native Doric was at somewhat difficult for southerners to understand. teacher he laid great stress upon thoroughness in taking and clinical examination, and maintained there was no better subject than neurology for teaching of clinical methods in general. His ability so well recognised at the London Hospital that in he was elected a supernumerary assistant ph there being at the time no vacancy on the staff.

He now decided to enter consulting practice; few, if any, can have attained success in that diff sphere in so short a time. He worked indefatig His precision of thought not only made him a diagnostician but enabled him to give clear-cut as to treatment, and his attention to detail him from neglecting any measure that was for his p benefit. Moreover, he possessed great charm of a warmth of feeling for people and an intuitive of their difficulties.

His election to the staff of the National Queen Square, added to his opportunities for te and he welcomed the international contacts which brought.

When the last war broke out Riddoch became head the E.M.S. neurological unit at Chase Farm H to which the neurological department of the Lo Hospital was evacuated. He had already been mad civilian consultant in neurology to the Army, and 1941 he accepted a commission and devoted hims to the organisation of the Army medical neurologi service. In this position he worked as unsparingly ever and did much to help those treating periph nerve injuries and traumatic paraplegia.

But he was a tired man when he took up this work and before long his health began to break down. He would not give in, but struggled on courageously, though latterly he must often have been in constant pain; and he was doing his hospital work and seeing patients till the week before his death.

Riddoch's place in neurology is secure, even though the very plenitude of his gifts came to favour the doctor at the expense of the investigator. In committee he was liberal in his ideas and wise in his counsel. His friends will recall his gaiety and humour; his stories, many of them Aberdonian, which set the table in a roar and at which he laughed himself till he had to wipe his eyes; and in quieter moments his love of fishing and the Rothiemay countryside, of birds, books, and, above all, music. But he lived for his work and died too young, because he spent his life so generously. It is hard to believe that he has hurried away for the last time.

W. R. B.

The untimely loss of George Riddoch will be grievously felt by his contemporaries and colleagues at Queen Square. I had the privilege of being his colleague at the National Hospital for over twenty years; years during which I came to have a deep respect for his generosity of mind and his sagacity in all the diverse problems which the life and work of a teaching hospital present to its medical staff.

In a special hospital, such as the National, there is a closer community of intellectual interests than is possible in a general hospital, and one comes to have a deeper appreciation of a colleague's personality and of his gifts, in consequence. From the time when

. H. R. Dean has been re-elected representative of the ity on the General Medical Council for a further five

rsity of London

Victor Dix has been appointed to the university chair ery at the London Hospital.

Dix received his medical education at the University of dge, the London Hospital, and Berlin, where he worked as ry assistant to Prof. A. von Lichtenberg. He qualified in d took his M.B. two years later, and the following year he d both his M.R.C.P. and his F.R.C.S. After holding house- ments at the London Hospital he became surgical first it, later joining the staff as surgeon with charge of out- s and assistant surgeon to the genito-urinary department. also lecturer in surgical pathology at the medical college. late war he was in charge of a urological centre in the Middle nd in 1946 he was appointed consulting surgeon to the South la command. He has published papers on calculus, hydro- sis, pyelitis, prostatic enlargement, and temporary drainage idney.

. Henry Barcroft has been appointed to the university f physiology at St. Thomas's Hospital.

Barcroft, who is 43 years of age, and is a son of the late ph Barcroft, was educated at Marlborough College and King's , Cambridge, where he obtained a first-class in both parts of tural sciences tripos. At Cambridge he was awarded the Fry and George Henry Lewis studentships, and at St. Mary's al, London, where he went to complete his medical studies, the Harmsworth scholarship. In 1932 he took the Conjoint ation and in the same year was appointed lecturer in ogy at University College, London. He took his M.B. the g year and his M.D. in 1935, the year in which he was also ted to the Dunville chair of physiology at Queen's University, . Professor Barcroft is a member of the North Ireland al Hospitals Council. His recent work, undertaken with . G. Edholm and others, has been largely concerned with the ion of blood-flow through muscle (*Lancet* 1944, i, 489; i, 513).

T. D. Day has been appointed to the university reader- pathology at St. Thomas's Hospital.

Day studied medicine at the University of Cambridge and g Cross Hospital, graduating M.B. in 1932. In 1936 he became stant pathologist at the Central Histological Laboratory of C.C. and in 1938 he was appointed research assistant to the professor of physic in Cambridge. From 1939 to 1945 he was rge of the laboratory of a general field hospital and since ilisation he has been lecturer in pathology at St. Thomas's.

T. Russell Fraser has been appointed to the university ship in medicine tenable at the Postgraduate Medical l of London.

Fraser graduated M.B. with distinction at Otago in 1932 e has held a New Zealand University travelling fellowship. 5 he was awarded the Hallett prize and three years later a feller travelling fellowship. He has also worked as a research at Harvard University. In 1940 he was appointed psychiatrist l Hill E.M.S. Hospital, where for the next two years he was rge of a team investigating for the Ministry of Home Security ychiatric effects of bombing, and he reported the results aper to the Royal Society of Medicine. In 1943 he became gator in charge of a team for the Industrial Research Board, 1946 he joined the staff of the Maudsley Hospital. Since he has been registrar and lecturer in medicine at the school. s published papers on insulin therapy and on Simmonds's e.

. C. J. O. R. Morris, PH.D., F.R.I.C., has been appointed e university readership in chemical pathology at the on Hospital. Since 1944 he has directed the chemical rch of the endocrine unit of the hospital, and since 1945 een chemist to the medical unit.

onal Boards' Appointments

ffield region: Dr. W. A. Ramsay (superintendent, psall Hospital, Manchester) has been appointed senior nistrative medical officer of the region.

uth-west Metropolitan region: For reasons of health Dr. neth Cowan will not after all take up his appointment as r administrative medical officer of this region. He will inue to serve as M.O.H. for Gloucestershire.

University of Glasgow

Mr. Walter Elliot, M.P., has been elected rector of the university. Mr. Elliot headed the poll with 1022 votes, and Dr. O. H. Mavor (James Bridie), the other medical candidate, was second with 521 votes.

University of Edinburgh

Mr. Norman Dott has been appointed to the new Forbes chair of neurological surgery.

Mr. Dott, who is 50 years of age, was educated at George Heriot's School, Edinburgh, and the University of Edinburgh, where he graduated M.B. in 1919. After holding house-appointments at the Deaconess Hospital, the Royal Infirmary, and the Royal Hospital for Sick Children in Edinburgh, he was awarded the Syme surgical fellowship in 1922. The following year with a Rockefeller fellowship he worked at the Peter Bent Brigham Hospital in Boston as a junior associate in surgery. On his return to Edinburgh he was appointed assistant surgeon to the Deaconess Hospital and to the Chalmers Hospital, later becoming neurological surgeon to the Royal Infirmary and Jordanburn Nerve Hospital. He is also lecturer in neurological surgery in the university. During the late war he was director of the neurological and neurosurgical brain injuries unit at Bangour E.M.S. Hospital, and consultant in neurological surgery to the Army in Scotland. His published work includes papers on the management of head injuries and on surgery of the brain and skull.

University of Aberdeen

Dr. John Craig has been appointed to the new chair of child health in the university.

Dr. Craig was educated at Robert Gordon's College and the University of Aberdeen, where his medical studies were interrupted during the 1914–18 war by his service as a lieutenant in the Royal Garrison Artillery. He graduated M.B. in 1921 with honours and held house appointments at Aberdeen Royal Infirmary and at the Hospital for Sick Children, Great Ormond Street. In 1922 with a George Thompson fellowship he worked at the Hôpital des Enfants Malades in Paris, and on his return to this country he spent several months in general practice in Keith. In 1924 he was appointed as assistant physician to the Royal Aberdeen Hospital for Sick Children, and the following year he obtained his M.R.C.P.E. and was appointed clinical tutor in the wards of the Aberdeen Royal Infirmary, whose staff he joined in 1932. From 1928 to 1935 he was also assistant in the department of medicine of the university. In 1937 Dr. Craig took up his present appointments of senior physician to the Royal Hospital for Sick Children, university lecturer in diseases of children, and consulting pædiatrician to the Aberdeen Maternity Hospital. His published work includes papers on spinal tumours and on malignant hypertension in childhood, on basophil adenoma of the pituitary, and on the treatment of calcinosis in children. He has also done research work on the incidence of acute rheumatism in Aberdeen and of recurrent bronchitis in children.

Dr. James Walker has been appointed lecturer in midwifery and gynæcology.

Royal College of Physicians of London

On Tuesday and Thursday, Dec. 9 and 11, at 5 P.M., Sir Arthur MacNalty will deliver the FitzPatrick lectures at the college, Pall Mall East, S.W.1. His subject is to be the History of State Medicine in England; in his first lecture he will deal with the medical department of the Local Government Board, and in his second with the foundations of the national health services.

On Oct. 18 the Bisset Hawkins medal was presented to Dr. C. H. Andrewes, F.R.S., for his researches in typhus and in influenza.

Royal College of Surgeons of England

On Thursday, Nov. 13, Sir Cecil Wakeley will deliver the Bradshaw lecture on Vogue and Fashion in Abdominal Surgery. On Friday, Nov. 21, Dr. I. Harvey Flack will give the Thomas Vicary lecture. He is to speak on Lawson Tait. Both lectures will be held at the college, Lincoln's Inn Fields, London, W.C.2, at 5 P.M.

Royal College of Physicians of Ireland

The following officers have been elected: *President*, Dr. Bethel Solomons; *censors*, Dr. Alan Thompson, Dr. D. M. Mitchell, Dr. M. Crowe, Dr. E. A. Keelan; *treasurer*, Dr. G. Bewley: *registrar*, Dr. T. P. C. Kirkpatrick. The president nominated Dr. Keelan as vice-president.

Royal Sanitary Institute

On Thursday, Nov. 6, at 10 A.M., in the City Hall, Belfast, Dr. Samuel Barron, Dr. W. G. Swann, and Dr. G. F. W. Tinsdale will open a discussion on the Control of the Manufacture and Sale of Ice-cream. On Saturday, Nov. 22, at 10.15 A.M., at the Town Hall, Dewsbury, Dr. E. D. Irvine will speak on the Local Authority and the Promotion of Health.

16; typhoid, 7; measles (excluding rubella), 1797; pneumonia (primary or influenzal), 531; cerebrospinal fever, 44; poliomyelitis, 276; polioencephalitis, 12; encephalitis lethargica, 0; dysentery, 46; puerperal pyrexia, 113; ophthalmia neonatorum, 67. No case *of cholera, plague, or typhus was notified during the* week.

Deaths.—In 126 great towns there were no deaths from enteric fever or scarlet fever, 1 (0) from measles, 2 (0) from diphtheria, 2 (0) from whooping-cough, 60 (2) from diarrhœa and enteritis under two years, and 11 (5) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 222 (corresponding to a rate of 27 per thousand total births), including 25 in London.

Diary of the Week

NOV. 2 TO 8

Monday, 3rd

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.2
6.15 P.M. Mr. J. Angell James: Acute Rhinitis.
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
4.30 P.M. *Epidemiology and State Medicine.* Dr. E. Ashworth Underwood: History of Cholera in Great Britain. Major-General Sir John Taylor: Cholera Control. Mr. P. Bruce-White: *Bacteriological and Immunological Aspects of* Cholera.
SOCIETY OF APOTHECARIES OF LONDON, Black Friars Lane, E.C.4
5 P.M. Dr. Peter Bishop: Hormone Therapy in Gynæcology.
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn Road, W.C.1
2.30 P.M. Miss D. J. Collier: *Facial Paralysis.*
ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh
8 P.M. Dr. John Gillies: Simpson—a Pioneer of Anæsthesia.

Tuesday, 4th

ROYAL COLLEGE OF SURGEONS
6.15 P.M. Dr. F. S. Cooksey: Physical Treatment in Otolaryngology.
SOCIETY OF APOTHECARIES
5 P.M. Prof. E. C. Dodds, F.R.S.: Hormones as Therapeutic Agents Apart from Gynæcology.
INSTITUTE OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. A. D. Porter: Vitamins in Skin Diseases.

Wednesday, 5th

ROYAL COLLEGE OF SURGEONS
6.15 P.M. Mr. Myles Formby: Acute Infections of the Pharynx and Parapharyngeal Space.
ROYAL SOCIETY OF MEDICINE
2.30 P.M. *History of Medicine.* Dr. H. P. Bayon: Karl Marx (1818–83)—His Ailments and Relations with Medicine.
8 P.M. *Surgery.* Sir Max Page: Surgical Records. (Presidential address.)
SOCIETY OF APOTHECARIES
5 P.M. Dr. R. R. Trail: Diagnosis and Treatment of Pulmonary Tuberculosis.

Thursday, 6th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Dr. Janet Vaughan: Anæmia Associated with Trauma and Sepsis. (Bradshaw lecture.)
ROYAL COLLEGE OF SURGEONS
6.15 P.M. Dr. Hugh Davies: X-ray Diagnosis in Otolaryngology.
ROYAL SOCIETY OF MEDICINE
8 P.M. *Neurology.* Dr. C. Worster-Drought: Charcot's Arthropathy. (Presidential address.)
UNIVERSITY OF LONDON
5 P.M. (1, Wimpole Street, W.1.) Mr. E. D. D. Davis: Applied Anatomy and Physiology of the Pharynx and Œsophagus. (Semon lecture.)
SOCIETY OF APOTHECARIES
5 P.M. Dr. James Craigie, F.R.S.: Virus Diseases—Treatment. (Second lecture.)
INSTITUTE OF DERMATOLOGY
5 P.M. Dr. G. B. Mitchell-Heggs: Erythemato-papular and Erythemato-squamous Eruptions.
HONYMAN GILLESPIE LECTURE
4.30 P.M. (Edinburgh Royal Infirmary.) Prof. G. F. Marrian, F.R.S.: Corpus Luteum Hormone.

Friday 7th

ROYAL COLLEGE OF SURGEONS
6.15 P.M. Mr. James Crooks: Sinusitis in Childhood.
ROYAL SOCIETY OF MEDICINE
10.30 A.M. *Otology.* Mr. Donald Watson: Mastoid Infection. (Presidential address.)
2.30 P.M. *Laryngology.* Mr. A. J. M. Wright: Milestones in Laryngology. (Presidential address.) Mr. Ian Robin: Snoring.
5.30 P.M. *Anæsthetics.* Dr. J. H. T. Challis: Teaching of Anæsthesia to Medical Students. (Presidential address.)
NATIONAL HOSPITAL, Queen Square, W.C.1
4.30 P.M. Prof. J. Lhermitte: Relation of Neurology to Psychiatry.
LONDON CHEST HOSPITAL, Victoria Park, E.2
5 P.M. Dr. R. A. Beaver: Anæsthesia for Thoracotomy.

Notes and News

THREE-POINT PLAN FOR NURSING

SPEAKING at Middlesex Hospital, London, on Oct. Mr. Aneurin Bevan, Minister of Health, described the of the Working Party on the Recruitment and Traini Nurses as the most stimulating and challenging docume nursing yet produced. The report, he said, was con with *long-term measures, and immediate action* mu taken towards: (1) reviewing factors likely to contrib wastage among nursing recruits; (2) relieving nur domestic work; and (3) part-time nursing. The p average rate of wastage of 54% among nursing recruits he held, indefensible. The use by some hospitals of for domestic work was unfair to other hospitals faced the prospect of having to close wards. On some points report, such as the duties and conditions of service *suggested new orderly grade, selection tests for student* better provision for training sister-tutors, more detailed was being undertaken before final decisions were Mr. Bevan said that over 12,600 nursing staff, incl 1740 midwives, had so far responded to the appeal for time service. There were now nearly 100,000 full-time 18,000 part-time domestic workers in hospitals, inclu nearly 3000 European volunteer workers; this was increase of some thousands since 1946.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY

THE annual meeting of this society, held in Rheinfeld Switzerland, on Sept. 10–14, was attended by memb representing nine countries. Dr. Barnes Burt (Bath) elected chairman of council, with Prof. Franistek Le (Prague), Dr. G. D. Kersley (Bath), and Prof. K. Walt (Geneva) as vice-chairmen. The treasurer is Dr. F. Clay (Leamington), and the secretary Dr. Donald *Wilson* (B

Subjects discussed included the neurohumoral effects irritation of the skin (Professor Staub); the physiology high altitude (Professor Verzar); spa treatment of sequelæ of poliomyelitis (Professor Fanconi); the treatm of asthma at an altitude of 5500 ft. (Professor Campe balneotherapy in the treatment of peripheral vascular orders (Dr. Wilson and Professor Lenoch); balneother with sulphur water in non-rheumatic diseases (Dr. Nichol and Professor Buergi); and spa treatment *in* rehabilitat after accidents and war injuries. The discussion on t last subject opened with a paper by Dr. McClellan, of Sarato Springs, outlining the scheme evolved by the Americ army during the war, for the use of spas in the reablement the injured, and emphasising the importance of continuing scheme during years of peace. Dr. Barnes Burt gave account of his experience with injuries during the war, read a communication from the U.S.S.R. on the treatm of frost-bite. *Demonstrations* were given at Schinzn Bad and Rheinfelden, and some of the visitors toured s in the Engadine, finishing at Locarno. Several sessions the society were held in the various spas, and a demonstrati of the treatment of poliomyelitis was given at Ragaz. Memb had much private hospitality offered to them, *both* by t Swiss members of the society and by the members of t Swiss Society of Medical Hydrology and Climatology.

This meeting coincided with the 25th anniversary of th I.S.M.H.; and despite the many difficulties it was unanimou agreed that it still plays a useful part in the internation recognition of balneotherapy.

HOW EUROPE FEEDS

A SPECIAL issue of *Picture Post* for Nov. 1 *describes* pictures and short articles the findings of a team investigators who have spent three months in studying the food position of Europe as seen in the homes of the peopl The main lesson that emerges is the contrasting position different countries.

Hospital for Diseases of the Skin

War damage to this hospital has now been repaired, and it is once more open for postgraduate *teaching.* Doctor are welcome as guests at the clinics held from Mondays to Fridays at 2 P.M., and on Tuesdays and Fridays at 5.30 P.M. Further details may be had from the secretary of the hospital, Blackfriars Road, S.E.1.

SIQUE AND GROWTH OF SCHOOLBOYS

G. E Friend
I.A. Oxfd, M.R.C.S.

E. R. Bransby
Ph.D. Lond
SOCIAL ECONOMIST,
MINISTRY OF HEALTH

investigation was started in 1936 to obtain informa- on the physique of adolescent schoolboys belonging milies of differing economic standing, and on the h of boys attending boarding-schools and day ls during school terms and holidays. There was no published information, apart from that of d (1935), on their growth and practically none on physique. Subsequent studies have been published lan (1937, 1939) and Widdowson and McCance (1944) owth in term and holiday, and by Orr (1936) and an (1939) on physique according to economic status. ring the seven school terms from September, 1936, ecember, 1938, we collected anthropometric data ys aged 11–18 years attending thirteen public ing-schools and six day secondary schools. The were to be weighed at the beginning, middle, and f each school term and measured in height at the ning and end of each term, and in chest girth each nber. Of the nineteen schools, thirteen followed rogramme, though all of them did not do so for the even terms. The other six schools varied from the amme in some particular, such as omitting the mid- weighing. The boys were weighed and measured ng shorts only; directions were issued to the cal-training instructors to ensure, so far as possible, form measuring of the chest in each school. The ge of chest girths at nipple level during expansion ontraction was taken as the chest girth, and the ence of these two measurements as the amount of expansion.

e average weight, height, and chest girth and nsion of boys in yearly age-groups in each school calculated from the measurements of the boys e respective ages taken during the whole period of tudy. Thus, in schools where the weighings were thrice a term the averages were based on twenty- sets of figures—i.e., three sets a term, for each of terms; for schools where the mid-term weighings not taken the averages were based on fourteen sets gures. The average ages of the yearly age-groups also calculated, and from these data the average its, weights, and chest girth and expansion at ly yearly intervals were calculated by interpolation. e thirteen boarding-schools were then divided into groups, A, B, and C, according to the school fees status, as a probable reflection of the economic ing of the parents of the boys attending the schools. classification is not the same as that based on the l standing of the school. It is appreciated that at some of the better-known public schools are attended cholars of different economic and social standing, t was thought that such a division would be adequate grouping the schools according to the economic ing of the parents. Two schools were classed as p A, of highest economic standing; seven schools as p B, of intermediate economic standing; and four ols, including Christ's Hospital, as group C, of lowest omic standing. The day secondary schools were dly of the same type, and no division according conomic status was possible. For each of the four ps—i.e., the three groups of boarding-schools and ay schools—averages for the different sets of anthro- etric data were calculated from the data of the schools prising the groups.

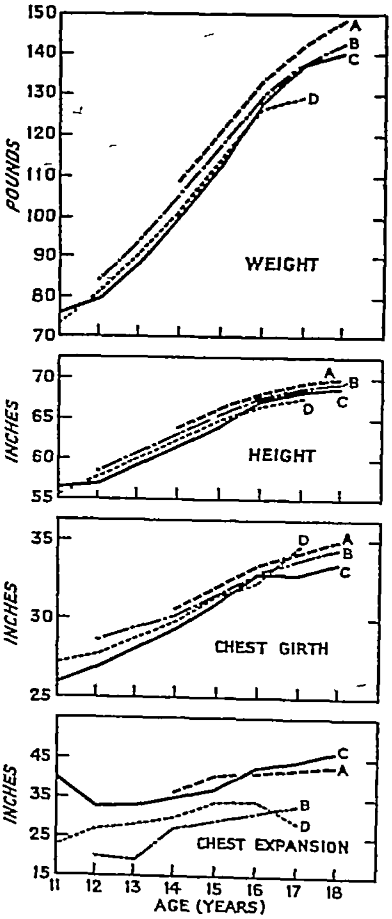
mong other aims we tried to find out whether the uations in growth-rates in different parts of the schools s and holidays were the same in boarding-schools as in day schools, and whether there were differences between individual boarding-schools and day schools. For those schools in which the boys were weighed at the beginning, middle, and end of each term a calculation was made of the number of boys who lost, gained, or remained stationary in weight in the first and second halves of each term and in the holiday, for each of the seven terms. From a scrutiny of the resulting figures it was decided that the data of boys of all ages and for the same parts of the different years could be combined to give a picture of the results for the individual schools as a whole. Few of the boys remained stationary in weight in the various parts of the year; so they were combined with those who gained weight, and it is the percentages for these two groups combined which are given in tables III and IV.

Two of the boarding-schools had some day boys, and in the analyses comparing growth during term and holiday the data of the day boys and boarders of these two schools were considered separately. One of the day schools had a few boarders, not sufficient, however, to warrant separate analyses for the day boys and boarders.

RESULTS

Physique According to Economic Status.—Table I and the accompanying figure show the average anthropometric data according to age for the four groups of schools and the number of boys on which the averages were based. The number of measurements on which the averages were based was many times the number of boys, because of the frequency with which the boys were weighed and measured.

Weight.—For boys aged 14–18 years the weights in group A exceeded those in group B, age for age, by 2·7–6 4 lb., the difference tending to become bigger at the older ages. The weight of group-B boys aged 12–18 years exceeded that of group-C boys of the same age by 1·2–6 1 lb., except that at 17 years the group-C boys were very slightly heavier. Throughout the age-range 13–18 years the differences between the group-C and day-school boys were not consistent, and taken as a whole there was probably no difference between these two groups. On the average the weight of the group-A boys exceeded that of



Average measurements according to age of boys and type of school. A, boarding-schools of highest economic standing; B, boarding-schools of intermediate economic standing; C, boarding-schools of lowest economic standing; D, day schools.

National Hospital, Queen Square

Prof. J. Lhermitte will deliver a lecture at the hospital, on Friday, Nov. 7, at 4.30 P.M., on the Relation of Neurology to Psychiatry. He will speak in English.

Dr. Jessie Macgregor Prize

This triennial prize, of the value of £75, has been awarded for the present period to Dr. Sheila Sherlock, for her work on liver, purpura, and malnutrition in the Ruhr.

New Zealand Appointment

Dr. F. Bielschowsky, who has been working in the department of pathology of the University of Sheffield under the British Empire Cancer Campaign, has been appointed director of cancer research for New Zealand.

Faculty of Homœopathy

A meeting of the faculty will be held at the London Homœopathic Hospital, Great Ormond Street, W.C.1, on Thursday, Nov. 6, at 5 P.M., when Dr. Andrew Kellner will speak on Artificial Hazards in Prescribing.

Factory Instals Mass-radiography Unit

A mass-radiography service, said to be the first to be installed by a factory, has been started by the Ford Motor Company at Dagenham. Examinations will be free and voluntary, and reports are to be confidential.

Lecture on Contraception

On Thursday, Nov. 6, at 2.30 P.M., at the Mothers' Clinics, 108, Whitfield Street, London, W.1, Mrs. Marie Stopes, D.SC., will give a lecture on contraception, and Dr. M. B. Bayly will afterwards give a demonstration. Admission by ticket only to be obtained in advance from the secretary of the clinics.

South-West Metropolitan Regional Board

At a meeting of psychiatrists of this region, it was resolved to form a psychiatric advisory group. The group will take the initiative in forwarding to the board proposals for the development of the mental health services in the region, and be available for consultation with the subcommittee on matters of psychiatric importance. Membership of the group is open to all psychiatrists in the region, and all who are interested are asked to communicate with Dr. T. P. Rees, of Warlingham Park Hospital, Warlingham, Surrey.

International Course for the Emergencies of Medicine and Surgery

This course, which met in Lisbon and Oporto from Oct. 1 to 15, was organised by the civil hospitals in Lisbon under the ægis of the Portuguese ministry of the interior. The British representatives who spoke were Sir Archibald McIndoe (Maxillofacial Injuries and Burns); Mr. H. A. Brittain (the Acutely Prolapsed Intervertebral Disc and Compound Fractures of the Femur); Mr. R. G. Pulvertaft (Tendon Injuries in the Hand); and Mr. H. Osmond Clarke (Compound Fractures and Rehabilitation).

Glasgow and West of Scotland Blood Transfusion Service

A symposium on blood-transfusion will be held by this service in the Royal Technical College, George Street, Glasgow, C.1, on Friday, Nov. 14, at 2.30 P.M. Discussions have been arranged on the Care of the Blood Bank (openers: Mr. G. R. Milne, Prof. J. P. Todd, PH.D.); Transfusion in Practice (Dr. J. Bruce Dewar, Dr. John Wallace); and the Importance of the Rhesus Factor (Prof. D. F. Cappell, Dr. A. W. Abramson). Further information may be had from the director of the service, 15, North Portland Street, Glasgow, C.1.

School Meals in London

The education committee of the L.C.C. has found itself unable to meet the growing demand for school dinners. It has therefore decided to experiment with a scheme of priorities under which some children will be given in rotation on one or two days each week a meal consisting of sandwiches and a sweet course; on the remaining days they will have the normal school dinner. The Ministry of Education have agreed to recognise these sandwich lunches as school meals for grant purposes; and an additional allocation of bread units has been secured.

British Psycho-Analytical Society

On Wednesday, Nov. 19, at 8 P.M., Prof. C. H. W F.R.S., will deliver the Ernest Jones lecture at 1, Street, London, W.1. His subject is to be Science Belief.

New York Academy of Medicine

The 1947–48 series of the academy's lectures to the includes addresses by Dr. G. R. Hargreaves on the of Leadership in War and Peace (Nov. 19); and by Raphael Cilento, M.D., on Food and Civilisation (Dec. Further information about the series may be had Dr. Iago Galdston, 2, East 103 Street, New York, 29,

Return to Practice

The Central Medical War Committee anno Mr. A. J. HERIOT, F.R.C.S., has resumed civilian 152, Harley Street, London, W.1 (Welbeck 9030).

Dr. W. W. Mushin, director of the department of thetics at the Royal Infirmary, Cardiff, attended the of Anæsthesiology in Buenos Aires between Oct. 20 at the invitation of the Argentine Association of A logy and under arrangements made by the British C

Dr. H. Graham Hodgson, director of the diagnostic department at Middlesex Hospital, London, is leaving three weeks' lecture tour in Turkey on behalf of the

CORRIGENDA. *Surgery of Hyperthyroidism.*—Our article of Oct. 4 said that in 1921 Dr. Frank H. Lahey mended complete thyroidectomy in cases of hyper with advanced cardiac failure. We understand that he never favoured complete thyroidectomy but the subtotal operation.

Whaling Today.—In last week's account (p. 639) discussion by the Universities Federation for Animal on methods of killing whales, Sir Robert Robinson, F.R. incorrectly reported as having spoken: the speaker Robert Robertson, F.R.S.

Births, Marriages, and Deaths

BIRTHS

BARWELL.—On Oct. 22, the wife of Dr. A. H. Barwell—a

BROWN.—On Oct. 22, at Colac, Victoria, Australia, the Dr. A. Graham Brown—a son.

DANIEL.—On Oct. 13, at Oxford, the wife of Dr. P. M. —a son.

FRANCIS.—On Oct. 15, the wife of Dr. R. S. Francis—a d

HASLER.—On Oct. 21, in London, the wife of Dr. J. K. —a daughter.

HENSON.—On Oct. 26, in London, the wife of Dr. R. A. He a daughter.

KENNEDY.—On Oct. 22, the wife of Dr. David Kennedy—a

MALLETT.—On Oct. 16, at Stourfield, Wimborne, Dorset, the Dr. A. E. de la T. Mallett—a daughter.

RICHARDS.—On Oct. 21, in London, the wife of Major H. J. Richards, R.A.M.C.—a daughter.

ROSE.—On Oct. 20, at Blackburn, the wife of Dr. D. J. —a daughter.

SHEPHERD.—On Oct. 17, at Birmingham, the wife of Dr. H. M. Shepherd—a son.

WALSH.—On Oct. 21, in London, the wife of Dr. R. Crosbie —a son.

MARRIAGES

MOON—LANG.—On Oct. 18, at Reigate, Anthony James M M.B., to Joan Vease Lang, M.B.

ODBERT—STOVIN-BRADFORD.—On Oct. 25, in London, F. Sidney Odbert, M.B., to Daisy Stovin-Bradford.

DEATHS

CROUCH.—On Oct. 10, in London, Harold Armstrong Cr O.B.E., M.C., M.A. Camb., M.R.C.S., D.P.H., lieut.-colonel

RIDDOCH.—On Oct. 24, in London, George Riddoch, M.D. A F.R.C.P., aged 58.

ıble III, a group-C boarding-school, has the highes of 94%, 87%, and 83% for the holidays, and the igures of 62%, 46%, and 32% for the first halves of erms. Another group-C school, no. 6 in table III, he high figures of 73%, 86%, and 74% for the first s of the terms. This consistency was noted for a school by Allan (1937). Taken as a whole, the for the boarders varied considerably from school hool, and to a greater extent than those of the oys. Thus, for the day boys, the numbers of those gained weight in the various schools varied from to 75% in the second half of the autumn term, 50% to 80% in the second half of the spring term, om 50% to 71% in the second half of the summer compared with 21–73%, 33–62%, and 21–66% boarding-schools.

schools 1 and 5 in table III data are available both arders and day boys who gained weight in the nd second halves of the terms and the holidays. ajor difference between these two groups of boys school was that one lived in the school and the it home. Hence there may have been differences n the groups not only in diet and sleeping condiut also in such matters as the amount of exercise hool hours. The number of day boys in school 1 boarders in school 5 was small, but a comparison attempted. The most marked feature is that in ond half of each term for each school, except autumn term for no. 5, the percentage of boys weight was greater by 6–20% for the day boys ed with the boarders. In school 1 there was ency for the percentages gaining weight in the lf of the term to be more for the boarders than day boys, but there was the reverse tendency ool 5.

DISCUSSION

man (1939) found that a group of public-school aged 14–18 years, compared with a group of ary-school boys in Durham, an area selected as ly affected by a severe economic depression and loyment, was about 30 lb. heavier and 3 in. and had a lumbar pull 30 lb. greater. Cathcart (1935) found that employed male adolescents were both taller and heavier than unemployed male adolescents, and that both groups were shorter and lighter than university students of corresponding ages. Orr (1936) showed that boys aged 13–18 years attending one public school were about 2 in. taller than Christ's Hospital boys, and that the latter were about 3 in. taller than the employed males of Cathcart et al. (1935).

The results of the above studies were obtained mainly by weighing and measuring the boys once only and are thus subject to variation according to the time of year at which the studies were made. Our results, based on data from nineteen schools and collected several times a year for two or three years, confirm that there are differences in the physique of adolescents according to economic class, though the differences were not so substantial as those found by Orr (1936) and Norman (1939). The public-school boys of both Orr and Norman were of better physique than our group-A public-school boys; the same school provided the data to both those workers, and that school would have been classed in group A in our study. This tends to confirm the superiority in physique of group A over that of group B. On the other hand, the physique of Norman's secondary-school boys was less than that of our day-school boys, perhaps because Norman's boys lived in Durham, a depressed area, whereas ours were drawn from six different localities. Further, there may be regional differences in physique which, for small samples, may exaggerate or diminish social class differences.

TABLE IV—PERCENTAGE OF BOYS GAINING WEIGHT

—	Summer holidays	Autumn term		Christmas holiday	Spring term		Easter holiday	Summer term	
		1st half	2nd half		1st half	2nd half		1st half	2nd half
Boarders ..	81	72	47	72	66	50	77	52	44
Day boys ..	82	75	62	74	75	65	69	58	62

We did not collect any data about the physique of employed or unemployed adolescents. However, the physique of each of our groups was better than that of employed and unemployed adolescents in 1929–32 (Cathcart et al. 1935). and of employed adolescents in 1943, as the following unpublished data (table V) collected by the Surveys Branch of the Ministry of Food show, when compared with the corresponding figures in table I. The adolescents in the Ministry of Food's body-weight survey were weighed and measured in indoor clothes and footwear, and the average heights and weights at the various ages must be reduced to enable a comparison to be made with our boys.

An interesting feature of the present study was the difference in physique between the groups of boarding-schools. The fees for all the boarding-schools, except Christ's Hospital and one other school in group C, ranged from about £100 to £250 a year. The boys must therefore have come from homes of good economic standing with good environmental conditions, such as food,

TABLE V—AVERAGE HEIGHTS AND WEIGHTS OF EMPLOYED ADOLESCENT MALES IN 1943: DATA COLLECTED IN THE MINISTRY OF FOOD'S BODY-WEIGHT SURVEY

Age (yr.)	Number	Av. height (in.)	Av. weight (lb.)
15	806	63·2	110·5
16	1310	65·4	121·2
17	1560	66·9	129·6
18	1240	67·3	134·4

The averages are based on data collected in April, July, and October, 1943. All measurements were taken in clothes and footwear.

d's Hospital, found that boys taking examinations ing scholarship work or other extra school activities more weight in the term than the average loss for espective ages.

e significance, from the health point of view, of the iations in the rate of growth during the term and ay has been discussed by Friend (1935), who states "my experience is that, provided a boy keeps his al rate of increase in weight at the beginning of school term, there is no need to worry about loss ight during the term, provided also that the loss ot go above the average loss of the school on the . In the very few cases where a boy weighs less beginning of one term than he did at the beginning preceding term there is obviously cause for investiga- It would, however, be valuable to obtain health ds and data on environmental factors such as diet, ity of exercise, and strain due to preparation for nations in schools with different patterns of growth ermine the relationship between them.

SUMMARY

a on the physique and growth during school terms olidays of boys attending thirteen public boarding- ls and six day secondary schools were obtained e period September, 1936, to December, 1938. boarding-schools were classed according to economic ing: A, highest; B, intermediate; and C, lowest. average height and weight of boys attending day s and group-C boarding-schools were about the but these were greater in group B, and still greater up A. In chest girth, group A were greatest, d by group B and day schools and then by group C. est expansion, group A and group C exceeded B and day schools.

ere were differences between the pattern of term and ay growth between boarders and day boys, the most ed difference being that a greater percentage of ders than of day boys did not gain weight in the second of each school term. There were greater differences een individual boarding-schools than between idual day schools.

e wish to thank the Leverhulme Foundation for a grant ne of us (G. E. F.) for this work; Mr. J. A. Strugnell, assistant master and games master at Queen Elizabeth's mar School, Barnet, and Mr. G. W. Murray, formerly tor of physical education, Mill Hill, and now director physical education, Marlborough College, for help in ing and executing the investigation; the headmasters of chools participating in the study, for permission to obtain growth records from the schools; the physical-training uctors, for weighing and measuring; Dr. H. E. Magee Major W. L. Giffard, for providing the dietary and other referred to in the discussion: and the Ministry of Food, roviding and allowing us to quote the data on the physique ployed adolescents in 1943.

THE PAROXYSMAL TACHYCARDIAS *

MAURICE CAMPBELL
O.B.E., D.M. Oxfd, F.R.C.P.
PHYSICIAN TO GUY'S HOSPITAL

(*Concluded from p. 647*)

Paroxysmal Ventricular Tachycardia

Ventricular tachycardia could be suspected on polygraphic curves (Mackenzie 1908), but its decisive diagnosis had to wait for electrocardiographic proof by Lewis (1909, short attacks with numerous extrasystoles; 1911, longer more ordinary attacks). In both of these forms of attack the auricular activity was undisturbed and easy to identify, but Hart (1912–13) recorded an attack where it was disturbed and there was retrograde condition with 2 : 1 block.

Gallavardin (1920, 1921, 1922) distinguished two varieties: the commonest occurring in seriously diseased hearts—the pre-fibrillatory type—and a less common one of no serious significance where the attacks were mostly short but very frequent with frequent ventricular extrasystoles also.

A sixth of my cases with cardiograms of the attack had ventricular tachycardia, and Hume (1930) gave the proportion as a fifth. But most of the 100 without cardiograms probably had supraventricular tachycardia; hence not more than 1 paroxysm in 15 is ventricular. Cooke and White (1943) collected their 27 cases from 25,000 patients with real or suspected heart disease, and at the same time used 750 patients with auricular tachycardia for discussing the prognosis. As four-fifths of all ventricular paroxysms occur in patients with serious heart disease, often with failure before the onset of their paroxysms, the proportion with ventricular tachycardia among those seeking advice because of their attacks will be still less—certainly not more than 1 in 50. Even with this small proportion a record of the attack to establish the diagnosis is important for prognosis.

ÆTIOLOGY

In four-fifths of the cases collected by Strauss (1930) the patients had serious heart disease. When his series are added to the 27 cases of Cooke and White (1943) and 15 of my own, 85 of 106 had serious heart disease and 21 were thought to have little else the matter with their hearts, though some had hyperthyroidism. Of those with heart disease 55% have congestive failure; 35% have a recent cardiac infarct and often both these factors; further, they have often been treated with digitalis. Levine (1945) found that 3% of patients with cardiac infarction had ventricular tachycardia soon after.

It was soon recognised that paroxysms were often caused by digitalis, not only by large doses but also by ordinary doses in a damaged heart. More than half the cases have had digitalis, and in more than a quarter—and in nearly all of the special bi-directional types—it was certainly the cause. Attacks have also been caused by adrenaline, atropine, and quinidine, and are not uncommon in severe diphtheria in children.

Ventricular tachycardia followed by standstill is the mechanism producing loss of consciousness in about a quarter of the cases of Stokes-Adams attacks, and ventricular tachycardia or fibrillation without standstill in another quarter.

Sex and Age Incidence.—Paroxysmal ventricular tachycardia is more common in men than in women. When the 94 reported cases of Lundy and McLellan (1934) are added to those of White and of myself, there were 95 men and 41 women—a higher male incidence than in the other paroxysmal tachycardias except flutter.

---

* The Lumleian lecture delivered at the Royal College of Physicians on April 16 and 18, 1946.

housing, clothing, and heating. A possible explanation of this difference in physique is that a genetic factor was responsible, in that boys of genetically superior physique went to group-A schools. It might well be, for example, that a school with a good sports record would attract boys of good physique. Knowledge of the schools in groups A and B, however, suggests that this was probably not the cause. Bearing on this, Jacob (1938) found that the physique of girls attending St. Paul's Girls' School, Hammersmith, where the social class level remained stationary, improved between 1907 and 1937. It may therefore be that, even among those groups of the population for whom environmental conditions are generally considered satisfactory, there is still room for improvement with subsequent improvement in physique. There is in fact no evidence that the full potential physique of the group-A boys was being achieved, because there was no higher standard with which they could be compared.

There seems, however, to be no doubt that the great bulk of the adolescent population is not growing to its full potential. If proper growth is an indication that a child is in good health and consequently better able to resist illnesses of different kinds—a hypothesis for which there is little direct but a good deal of indirect support—it is interesting to speculate to what limits illness-rates among adolescents would be reduced if the environmental conditions were such as to enable the full potential physique to be achieved.

Three studies have been reported on the variations in growth-rates of boys during school terms and school holidays. Allan (1937, 1939), from data of about 1000 boys attending two secondary schools in Leeds in 1937–38 and from data from a small public school of 60–90 boys in the South of England during 1923–32, found a sudden decline in weight in the final month of each term. Widdowson and McCance (1944) found that in two well-known boys' public schools growth in height and weight was much more in the holidays than in the terms, but that in another public school growth was about the same in the terms as in the holidays. Allan, and Widdowson and McCance suggest that the poor growth during the terms was the reflexion of unsatisfactory environmental conditions in relation to the boys' needs. Our results lead to the conclusion that some factors of boarding-school life were responsible both for the differences between the boarding-schools and day schools and between the individual boarding-schools. In the war-time studies on growth by the Ministries of Education and Health (Bransby 1946) it was found that children living in residential camp schools did not grow so well as those living at home.

Data from another well-known boys' boarding-school not included in the present study have some bearing on the differences in growth during term and holidays. In 1934 Dr. H. E. Magee (personal communication), in a week's dietary survey in this school, found that a good diet with a great deal of variety was provided, including ten different varieties of meat, four kinds of fish, fifteen kinds of vegetable, and nine kinds of fruit. The boys could have as much as they liked of most foods and also had access to a tuck-shop. The average consumption of milk was about $^3/_4$ pint a day and of eggs just less than one a day. The diet provided 3300 calories, 106 g. of protein, 1 g. of calcium, 1·6 g. of phosphorus, and 21 mg. of iron per boy per day. No calculation was made of the vitamin content of the diet; but, from the amounts of foods consumed, it was likely to be considerable. Judged by the League of Nations' standard of requirements the diet was excellent. Between 1934 and 1939 the same kind of diet was provided under expert supervision.

TABLE VI—AVERAGE GAINS IN WEIGHT (LB.) PER
IN TERMS AND HOLIDAYS IN ONE BO
ACCORDING TO AGE

Age-group	Autumn		Spring		Summer

Two other matters relating to environmental conditions need to be mentioned. First, in the summer term of 1937 there was an influenza epidemic affecting three-quarters of the boarders. It began mildly became severe, and many of the boys were
Second, in the Michaelmas term of 1936 there changes in sports training involving greater strain than in previous years.

Table VI shows the monthly growth-rate in *during school terms and holidays for 1934–38,* in age-groups. The growth in the holidays was better than that in the term, this being parti *conspicuous for the summer term and* holidays. boys of all ages it was customary, on the av lose weight during the summer term. There were considerable differences in the growth pattern from to year. Thus, for all age-groups, growth in Michaelmas terms of 1934 and 1935 was greater than that in the Michaelmas terms of 1936 1937. This may have been due, to some extent, to greater physical strain arising from the modified training, a suggestion substantiated to some extent the data for the Lent term of the same years. influenza epidemic in the summer term of 1937 does appear to have reduced the average gain in weight that term compared with the same term in other This may have been due to a cessation of cricket, ming, and other activities during the period of valescence. For boys aged 15–18 years the annual in weight varied considerably from year to year. T for boys aged 15, 16, and 17 years the gains in 193 exceeded those in 1936–37 by 45%, 21%, and respectively.

The interesting point arising from these data is that *considerable losses in weight took place in the* term despite the fact that the boys were well Mumford (1927) remarks on the effect of physical mental strain on the development of children. In 191 the ordinary school physical instruction was in Manchester Grammar School, as was the routine work of preparing for higher examinations. The appearance of the members of the Officers' Training C was noticed when the boys returned from the drill at the end of the afternoon, and inquiries showed the weight and measurements of the cadet group fallen below those of the non-cadet group. % magnesium sulphate intravenously. Morphine
desirable in ordinary recurrent attacks but may be
and may be effective if an attack lasts long and is
ng serious anxiety.

e cessation of attacks after digitalis has often been
ved, but it is doubtful if it is effective, and generally
uld not be given, unless indicated apart from the
ysms—e.g., by the development of failure in a
attack. But if the attack is thought to be flutter,
digitalisation is indicated.

oxysmal Auricular Fibrillation.—Quinidine in small
oderate doses is the treatment of choice. The arrest
roxysms by stimulation of the vagus has been
ted, but there does not seem to have been much
matic trial of this method. If the paroxysm is long.
most important to try and stop it with quinidine;
er these conditions full doses up to 0·8 g. three times
o-hourly intervals should be used.

e tendency for digitalis to favour the onset of
llation has been taken as a valid reason for not using
the treatment of such paroxysms. But they may
opped by it—not only short attacks where digitalisa-
is far from complete but also attacks of some days'
ation, where it is being given in fairly large doses.
does digitalis always convert paroxysmal to
blished fibrillation with ease; in some patients it
s the paroxysms and in others reduces their
uency.

aroxysmal Auricular Flutter.—The treatment of
e is digitalis. It should be given in full doses and
ted at once when flutter changes to fibrillation.
en the rhythm will then revert to normal; and,
n if it does not, the patient is generally better and
e easily controlled with regular digitalis. Some-
es it does not produce fibrillation, or flutter returns.
idine should then be tried in the same amounts as
fibrillation, provided the state of the heart is no
tra-indication.

Ventricular Tachycardia.—The treatment here is quinidine 0·4 g. repeated after two hours up to three or even five doses. Riseman and Linenthal (1941) have found intramuscular injection of quinidine bihydrochloride 0·5 g. in 5 ml. of water, repeated after two hours, effective in many cases where quinidine by mouth had failed. Bunn (1933) and Hepburn and Rykert (1937) reported favourably on the use of intravenous quinidine 4 g. (gr. 60) dissolved in 500 ml. of 5% glucose given at the rate of 100 ml. an hour. Magnesium salts (2–4 g.) intravenously may also succeed. Mecholyl has been used, but it is certainly dangerous and can only be recommended for young patients with normal hearts.

AFTER THE PAROXYSM

The first thing is to decide the nature of the underlying disease, if any. If thorough examination justifies it, reassurance about the nature of the attacks is sometimes all that is called for, and this alone may help to reduce their incidence. In fibrillation and flutter the possibility of hyperthyroidism must never be overlooked, for its correction by thyroidectomy often gives complete relief.

Dietetic and toxic factors must also be considered, and their treatment will sometimes succeed, though too much should not be expected of this. The avoidance of large meals will sometimes help. Similar considerations apply to the abuse of alcohol and tobacco, and reduction or even withdrawal will be found useful in a few cases. Work and exercise must also be reviewed, and in auricular tachycardia exercise may need increasing as well as diminishing when the heart is otherwise normal. A mild sedative may prove very useful.

If in spite of this the attacks are frequent and troublesome, the regular administration of quinidine 0·4 g. t.i.d. or less may greatly reduce or abolish the attacks. This may be effective in paroxysms of all sorts, least so perhaps in auricular tachycardia. So, besides its use in restoring normal rhythm, quinidine has won a rightful place in reducing the frequency of paroxysms. Occasionally the improvement is maintained when quinidine is withdrawn. Quinidine sometimes prevents fibrillation from becoming established.

Regular digitalisation has been recommended in paroxysmal auricular tachycardia, but it is rarely indicated and has not been useful in our experience. In ventricular tachycardia it must be avoided, as it is often the cause of attacks. In paroxysmal fibrillation digitalis has a more important place, though it should not be used till quinidine has failed. The production of fibrillation by digitalis has already been discussed, and it is only when the risk of established fibrillation has been accepted or is desired that digitalis should be used. Even then it is not always easy to produce fibrillation, and sometimes the attacks may be reduced.

SUMMARY

The paroxysmal tachycardias are an inconvenience rather than a sign of heart disease.

The prognosis should be judged by the state of the heart in the free intervals and not by the paroxysms.

Though ventricular tachycardia most often occurs with serious heart disease and is, in this sense only, of grave import, even it, and still more the other varieties, may occur with a normal heart and be of no significance for prognosis.

It is important to distinguish the different varieties, because the most effective treatment is somewhat different.

Often the condition cannot be cured, but generally treatment helps in reducing the length and frequency of attacks.

(*References at foot of next page*)

Most cases occur between the ages of 40 and 70 (Campbell unpublished, Strauss 1930, Cooke and White 1943). The last series (27 cases) and my own (15 cases) have been tabulated separately: under the age of 40 there were 8 with normal hearts and 3 with heart disease; over 40 there were 2 with normal hearts and 29 with heart disease.

SYMPTOMS

Generally the patients are already seriously ill, and the rapid rate may be the last straw for a heart already overburdened, but even so the symptoms may sometimes be slight. Where the patient was in good health before the attack, the symptoms are the same as in auricular tachycardia.

THE RATE

This does not help in distinguishing ventricular and auricular tachycardias. The faster rates were found with more healthy hearts, perhaps because they alone can survive long at these rates. Levine and Strong (1923) thought that some irregularity during ventricular paroxysms might help the diagnosis on clinical grounds alone. Sometimes, especially at the start, the rate is a little irregular, speeding up from 150 to 190 or falling from 270 to 220 in a few seconds, and a slight irregularity may be found on measurement, especially in paroxysms interrupting auricular fibrillation or when the patient is moribund (Cooke and White 1943). Any obvious irregularity, however, is likely to indicate paroxysmal flutter with various degrees of block.

DURATION OF PAROXYSMS

Very short paroxysms lasting a few beats are much more common than with supraventricular tachycardias, occurring sometimes in half the cases. Nevertheless in longer attacks of over four days ventricular tachycardia is also proportionately more common, though still only a small minority of all attacks of this length. The longest attack I have seen lasted sixteen days; Elliott and Fenn (1934) reported one of thirty-two days, and White one of four or six weeks.

PROGNOSIS

The cases must be divided into a small group with no heart disease and a large group with organic heart disease, generally serious. Following Gallavardin, Strauss (1930) found that the prognosis was good in patients with no heart disease but extremely bad in those with organic heart disease, 80% having died in an average period of only twenty-four days. Cooke and White found two groups of those with heart disease: half of them dying within three weeks of the paroxysms; and half making an immediate recovery and dying, sometimes suddenly, a few months later, the longest having lived eighteen months. Of the 5 with hearts that were normal, 4 were known to be alive from two to fourteen years later.

Of my own patients 8 have died, but in 6 of these death was to be expected from their heart disease. On the other hand, a woman of 56, with auricular fibrillation and frequent short and longer paroxysms in which she was incapacitated, was to my surprise much the same five years later; 4 others were of the type described by Gallavardin (1922) with numerous extrasystoles and short attacks. In none of these did the attacks seem of any significance for prognosis.

A third small but important group should be distinguished: patients apparently without much the matter except these paroxysms, who can only be diagnosed electrocardiographically, but with a grave prognosis owing to the risk of ventricular fibrillation. Gallavardin and Froment (1930) described such a case, and a similar mechanism probably explains some of the unexpected deaths among reported cases. Because of this possibility the outlook in ventricular paroxysms is more serious, and this is one reason for trying to obtain an gram of the paroxysm; fortunately they are rare.

Treatment

Some considerations common to all the will be taken first. The treatment of the patient attacks and the attempt to prevent their must be distinguished.

Quinidine is used so often that, to save repetition, points about it will be considered here. When diagnosis has been made, even between attacks, a dose of 0·2 g. should be given to detect any If this is all right, 0·4 g. may then be prescr repeated after two hours. These will be referred "small doses" and may safely be entrusted to the

If the attack persists, the dose may be giving the same amount at two-hourly intervals —i.e., 2 g.—but this should be done for the with the patient under observation and should be up to, except in an emergency. These will be to as "moderate doses."

Large doses—i.e., more than this—should only by those with experience of quinidine. The tion in the blood will be increased more giving 0·8 g. or even 1·0 g. three times at the usual hourly intervals. As soon as quinidine has normal rhythm it may be omitted, unless reasons for thinking the paroxysms likely to the near future.

Between attacks, when quinidine is used to them, the object is not to reach a high level but the quinidine constantly effective. The dose therefore not be at two-hourly intervals but through the day in three or four doses; 0·4 g. may be taken as the routine, but more may be

DURING ALL FORMS OF PAROXYSM

Rest should generally be advised, but past with a particular patient may show that relative enough. Bed is rarely needed, unless special or the condition of the heart at other times advisable. Reassurance will take an important as the prognosis is good. If an attack persists evening, rest in bed and a sedative or hypnotic often lead to its arrest. Other treatment will on the variety of the paroxysm.

Supraventricular Tachycardia.—Vagal stimulation pressure over the carotid sinus is perhaps the known method. Pressure should be maintained for a minute or so over the slight swelling of the just before its division into its two branches above omohyoid, where the artery comes out from under sternomastoid to lie in front. The vagus is lying external to the carotid. Pressure on either side successful, perhaps more often on the right. on the eyeball, invoking the oculocardiac reflex, may be effective.

But all patients cannot apply these methods. something that the patient can do himself is Tricks of sudden movement—e.g., bending down open a low drawer, and putting the head between knees—will often be effective; provided the succeeds once he will generally do so again and cease to be worred about his attacks. A forced tion with a closed glottis after a deep inspiration is constantly effective.

Quinidine in small or moderate doses is probably most useful drug. Such remedies will have their in the early phase of the paroxysm. The only risk of attack is its prolongation so that thrombosis and emb or congestive failure develop, and every attack four days should be regarded as a medical for admission to hospital or for treatment by with much experience of this disorder. In this way it remained about 11 st. 9 lb. The blood-pressure d the same, and there was no alteration in the physical

symptoms persisted irregularly during the ensuing despite administration of œstroform parenterally roid gland by mouth. An electrocardiogram revealed s deviation and inversion of P3 and T3. Her weight between 12 st. in August, 1938, and 11 st. $8^{1}/_{2}$ lb. in er, 1938, deep X-ray therapy to the left suprarenal ing followed by a return of menstruation in November year.

g 1939 further deep therapy was given to the supra- eas, and menstruation continued until November; but ary, 1940, her weight had increased to 12 st. $5^{1}/_{2}$ lb., l reappeared over the trunk, and her former symptoms d and remained despite another course of deep X-ray . She had swelling of the feet and ankles, swelling of uth, some dimness of vision, insomnia, numbness of ers, cramps in the feet, pain in the back and abdomen, daches. She was readmitted to hospital on March 6,

blood-pressure was now 230/145 mm. Hg, and the howed some enlargement. There were numerous neous ecchymoses on the arms and legs. Radiography turcica, suprarenal area, and chest showed nothing al. Bleeding and coagulation times were prolonged, blood-platelets numbered 89,000 per c.mm. The howed a hypertensive neuroretinitis, with woolly of exudate and hæmorrhages. The visual fields were ed. Blood chlorides 496 mg., phosphates 3·6 mg., olesterol 220 mg. per 100 ml. Urine contained a large t of albumin and many hyaline and epithelial casts. tient became almost completely blind, and after severe of cardiac asthma she died on May 14, 1940.

tions stained with hæmatoxylin-eosin, Weigert's hæma- n-van Gieson, Weigert's elastin, and Crooke's modifica- of Mallory's acid-fuchsin aniline-blue method.

prarenals (fig. 2).—Hyperplasia of cells of cortex; normal arrangement largely retained. Zona glomerulosa narrow, zona fasciculata very wide, and zona reticularis slightly wider than normal. Except in zona glomerulosa, cells heavily loaded with lipoid. Medulla normal and small in amount.

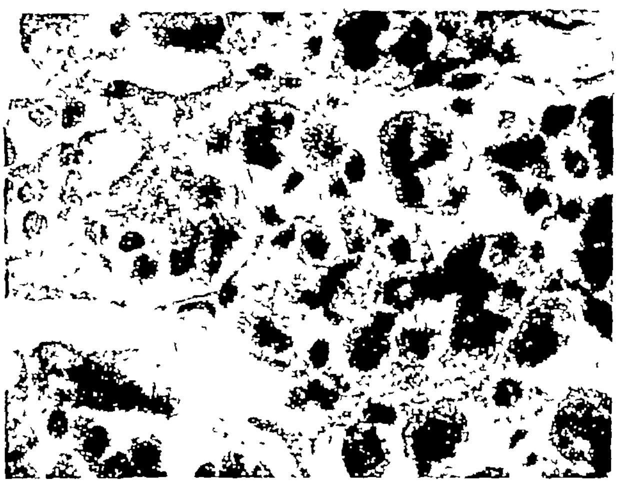

Fig. 3—Photomicrograph of pituitary gland showing hyaline change and vacuolation in basophil cells. (× 735.)

Pituitary.—Cyst in posterior lobe lined by ciliated columnar epithelium: appeared to have arisen in hypophyseal stalk. Separated from pars intermedia by small rim of posterior-lobe tissue. Relative proportions of acidophil, basophil, and chromophobe cells in anterior lobe apparently normal. Well-marked hyaline change in cytoplasm of basophil cells (fig. 3), many of which contained vacuoles. From most of these cells granules had disappeared, but a few showed a rim of granules at the periphery. No fine vacuolation of granules noted. No adenoma seen. No basophil cells in posterior lobe, which apart from cyst was of normal structure.

Kidneys.—Hyaline thickening of intima of afferent arterioles. In interlobular and medium-sized arteries intimal thickening and reduplication of internal elastic lamella, with narrowing of lumen. Glomerular atrophy, with hyaline fibrosis of Bowman's capsules and degeneration of tubules, beside areas of normal-looking renal tissue. Picture one of nephrosclerosis in essential hypertension.

Pancreas.—Hyaline thickening of intima of arterioles; smaller arteries sclerosed, with reduplication of internal elastic lamella. Parenchyma and islets of Langerhans normal.

Thyroid.—Hyperinvolution, with accumulation of colloid.

DISCUSSION

The clinical features initially pointed to the pituitary as the site of the disorders; and, as the right-sided suprarenal shadow could not be confirmed, it was decided to begin radiotherapy to the pituitary gland. Subsequent treatment and its effect is summarised in the table.

Date	Tissue dosage	Effect
January, 1936	1000 r to pituitary	No improvement

PATHOLOGIST

ROYAL MELBOURNE HOSPITAL

From the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne

THE disease formerly known as Cushing's syndrome and now generally recognised as pituitary basophilism occurs, as Crooke (1935) has pointed out, in three distinct groups of cases: there may be (1) a basophil adenoma in the pituitary gland, (2) a neoplasm of the thymus, or (3) a neoplasm or hyperplasia of the suprarenal cortex without either basophil adenoma or thymic neoplasm. All three groups, however, show the same hyaline change in the basophil cells of the pituitary gland.

In the following case pituitary basophilism was associated with hyperplasia of the suprarenal cortex and a cyst in the posterior lobe of the pituitary.

CASE-RECORD

A woman, aged 23, was admitted to the Royal Melbourne Hospital on Nov. 22, 1935, with a history that in ten months her weight had increased by 22 lb. and her face, neck, and trunk had become larger, the waist line increasing by 5 in. During this period hair appeared on her back, abdomen, and limbs, and her skin became coarser. Her menses had been normal until two months before admission, since when there had been amenorrhœa. For three months she had had a sensation of pressure between the zygomata, with momentary hot flushes; but she had no headache. Sleep, appetite, and bowels were normal; there had been slight frequency of micturition. Childhood had been healthy. Her appendix was removed in 1931, and an abscess of the umbilicus was six months before admission.

Investigation

The patient was a large-faced sensible girl, with a beard and a growth of coarse hair on the limbs and (fig. 1). The pubic hair showed a male distribution. The also was of the male type, with the shoulders broader t hips. There was a well-marked increase of the subcut tissue of the face, neck, and trunk, but not of the Temperature 98°F; pulse-rate 70 per min., pulse full regular; respiratory rate 22 per min.; blood-140/90 mm. Hg. The breasts were small, and the skin trunk was coarse and greasy.

No abnormal physical signs were found in the heart lungs. There was some tenderness on the right side abdomen over the kidney. The vaginal orifice was ve making an examination of the genitalia difficult. Ex of the nervous system, and chemical and microscopical nation of the urine showed no abnormality. Glucose t test normal. The pituitary fossa had normal radi outlines. Basal metabolic rate −18%. A blood-count no abnormality except a slight shift to the left in the series. Blood-urea 20 mg., blood-cholesterol 175 m blood-calcium 11·8 mg. per 100 ml. Urea concen 3·75% in the third specimen. Chloride-balance tests n Visual fields and fundi normal. On radiography an ir rounded shadow was seen overlying the upper pole right kidney. This was thought to be consistent wi suprarenal tumour, but subsequent radiography did confirm the finding. Intravenous pyelograms showed n renal outlines and function. The patient was discha continued to gain weight.

Treatment and Progress

In February, 1936, deep X-ray therapy to the pit region was begun but had no beneficial effect, and in purple striæ over the iliac crests and in the right axilla noted. In April it was decided to give a course of X-ray therapy to both suprarenal areas. Her increased from 10 st. 10 lb. on Feb. 20, 1936, to 11 s on Aug. 31, 1936, but on this day she reported the rence of a normal menstrual flow after amen which had lasted twelve months, and some improv in her general state of health and in her physical st

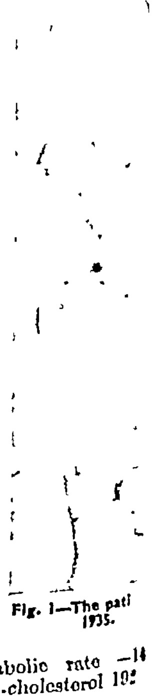

Fig. 1—The pati 1935.

During the succeeding year menstruation was normal, but there were frequent backache, headache, and generalised pains. The abnormal hair was progressively but not completely lost. Menstruation ceased again in August, 1937; hirsuties recurred; and her weight, which had fallen to 10 st. 13 lb. in December, 1936, rose to 11 st. 9 lb. by October, 1937. Examination under general anæsthesia in November revealed a small underdeveloped anteverted mobile uterus. The right ovary was small, and the left very small.

Deep X-ray therapy to the right suprarenal area in November, 1937, gave no benefit, and she was readmitted to hospital on Feb. 10, 1938. At this time she was complaining of unsteadiness in the legs, constricting pain in the chest, radiating to the back, and headache. She had been very short of breath, especially on exertion, and had a feeling of pressure in the throat. The growth of hair had increased, and amenorrhœa continued. She had had occasional cramp-like pains in the legs. There was no alteration in the physical signs, and the blood-pressure was 130/80 mm. Hg. Blood-urea 43 mg. per 100 ml.; urea concentration 3·20% in the third specimen. Basal metabolic rate −1 Aschheim-Zondek test negative. Blood-cholesterol 19 per 100 ml.

Deep X-ray therapy was given to the pituitary re without improvement. For the next three months the in the chest, back, and head continued, and pain in the fin wrists, and ankles developed. She felt drowsy and could walk without feeling tired. Her appetite was poor but

ted. Blood chlorides 496 mg., phosphates 3·6 mg., olesterol 220 mg. per 100 ml. Urine contained a large t of albumin and many hyaline and epithelial casts. atient became almost completely blind, and after severe s of cardiac asthma she died on May 14, 1940.

psy

rt weighed 460 g.; hypertrophy of left ventricle; e pale red and firm; cavities dilated; valves normal; ary arteries patent but with moderate atheroma; aorta atheromatous.

gs normal apart from congestion and œdema. Perim and alimentary tract normal. *Liver* large (1920 g.), rownish-red, with a regular pattern. *Gall-bladder, spleen, ancreas* normal. *Kidneys* normal in size (120 g. each), g readily, leaving a red mottled surface. On section, narrowed in places, medulla fairly wide, substance ed and firm; vessels somewhat thickened and pyramids what irregular. *Uterus* small and fibrous; *ovaries* small trophic. *Skull* and *brain* normal. *Thyroid* gland normal ze, with several small colloid areas; red and fleshy. *ymic tissue.*

th *suprarenals* bright yellow, firm, and very large (each ·5 × 1 c.cm.); combined weight 20·5 g. Cortex wide, hypertrophy; medulla apparently normal; no tumour .

la turcica normal in size; *pituitary gland* small, filling Anterior lobe yellowish, soft, and uniform; posterior replaced by small cyst (0·9 cm. at largest diameter) ining mucoid material.

oscopy

ctions stained with hæmatoxylin-eosin, Weigert's hæmalin-van Gieson, Weigert's elastin, and Crooke's modification of Mallory's acid-fuchsin aniline-blue method.

prarenals (fig. 2).—Hyperplasia of cells of cortex; normal l arrangement largely retained. Zona glomerulosa

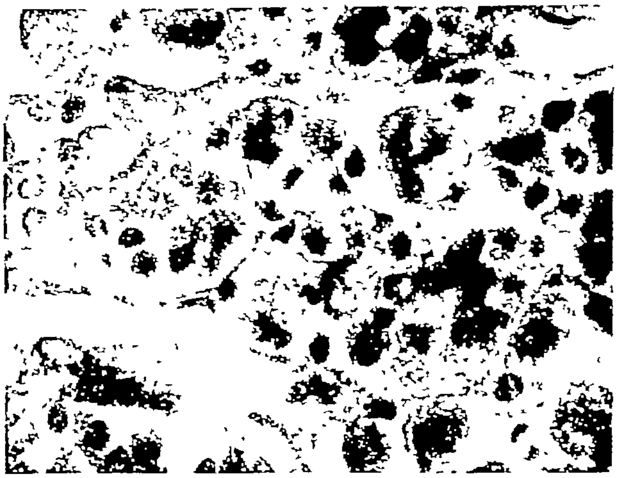

Fig. 3—Photomicrograph of pituitary gland showing hyaline change and vacuolation in basophil cells. (× 735.)

narrow, zona fasciculata very wide, and zona reticularis slightly wider than normal. Except in zona glomerulosa, cells heavily loaded with lipoid. Medulla normal and small in amount.

Pituitary.—Cyst in posterior lobe lined by ciliated columnar epithelium: appeared to have arisen in hypophyseal stalk. Separated from pars intermedia by small rim of posterior-lobe tissue. Relative proportions of acidophil, basophil, and chromophobe cells in anterior lobe apparently normal. Well-marked hyaline change in cytoplasm of basophil cells (fig. 3), many of which contained vacuoles. From most of these cells granules had disappeared, but a few showed a rim of granules at the periphery. No fine vacuolation of granules noted. No adenoma seen. No basophil cells in posterior lobe, which apart from cyst was of normal structure.

Kidneys.—Hyaline thickening of intima of afferent arterioles. In interlobular and medium-sized arteries intimal thickening and reduplication of internal elastic lamella, with narrowing of lumen. Glomerular atrophy, with hyaline fibrosis of Bowman's capsules and degeneration of tubules, beside areas of normal-looking renal tissue. Picture one of nephrosclerosis in essential hypertension.

Pancreas.—Hyaline thickening of intima of arterioles; smaller arteries sclerosed, with reduplication of internal elastic lamella. Parenchyma and islets of Langerhans normal.

Thyroid.—Hyperinvolution, with accumulation of colloid.

DISCUSSION

The clinical features initially pointed to the pituitary as the site of the disorders; and, as the right-sided suprarenal shadow could not be confirmed, it was decided to begin radiotherapy to the pituitary gland. Subsequent treatment and its effect is summarised in the table.

Date	Tissue dosage	Effect
January, 1936	1000 r to pituitary	No improvement
March, 1936 ..	600 r " "	" "
May, 1936 ..	1200 r to right and left suprarenals	Immediate improvement, maintained for 14 months
November, 1937	3100 r to right suprarenal	No improvement
March, 1938 ..	2400 r to pituitary	" "
July, 1938 ..	2500 r to left suprarenal	Immediate improvement
November, 1938	1750 r to left suprarenal	Improvement maintained
May, 1939 ..	1850 r to left suprarenal	" "
January, 1940	1520 r to left suprarenal	No improvement (Death in May, 1940)

It will be seen that irradiation of the pituitary did not bring improvement. Irradiation of both suprarenal gland areas in one field did so; but later radiation of one, the right suprarenal, did not reproduce the benefit, which was later again produced and maintained by irradiation of the left suprarenal. Finally the glandular symptoms recurred and renal failure took place.

Clinically this sequence seemed to justify the diagnosis of a left-sided suprarenal lesion; yet necropsy showed identical cortical hyperplasia in the two suprarenals. We can think of no reason for the failure of right-sided irradiation and the success of slightly smaller dosage directed to the left side. The possibility that a left-sided tumour was eradicated by the tissue dosage (2500 r) given in March, 1938, cannot be seriously considered, in view of the final recurrence of the original symptoms, the absence of tumour, and the bilateral cortical suprarenal hyperplasia found at autopsy. The higher tissue dosage given in the second and third courses to the suprarenal glands was an attempt to produce a maximal recession on a suprarenal tumour thought to be present.

Relation of Renal Damage to Irradiation.—The kidney is susceptible to damage by large doses of X rays. The initial changes are those of damage to the renal epithelium and to the vascular endothelium, and the epithelium of the convoluted tubules is said to be most sensitive. Œdema of the kidney, with vascular dilatation and degeneration and atrophy of the epithelial cells, is followed by diffuse fibrosis, thickening of the blood-vessels, and hyalinisation of the glomeruli; a contracted kidney results. Clinically these changes produce a syndrome of chronic nephritis with hypertension, retinitis, and albuminuria. The question therefore arises whether the irradiation had any ætiological connexion with the terminal nephritis and hypertension found in this case.

Assuming that each kidney received the same dosage as the corresponding suprarenal gland, the right kidney received two courses—i.e., 1200 r tissue dose, followed by 3100 r six months later—whereas the left kidney received tissue doses of 1200 r, 2500 r, 1750 r, 1850 r, and 1520 r, a total of about 9000 r in $3^1/_2$ years. Dosage of this order might cause degeneration, though the cumulative dosage is much less than that causing gross damage in the case described by Stanford Cade (1940), in which a dose of about 5000 r was administered during 50 hours by means of a radium bomb. But if the irradiation was responsible for the damage, one could expect this to be more obvious in the left kidney, which received more than twice as much as the right. The fact that the two were of identical size and weight (120 g.), and showed pathological changes of the same degree, makes it most unlikely that any significant renal damage was caused by the X-ray therapy, or that the malignant hypertension was originated by the irradiation. The renal failure of this case falls into its proper place as one well-recognised feature of Cushing's syndrome.

SUMMARY

In a young woman the symptoms of pituitary basophilism were not relieved by irradiation of the pituitary gland or of the right suprarenal gland. Considerable benefit, however, was obtained from irradiation of the left suprarenal.

At necropsy the condition of the two suprarenals (cortical hyperplasia) was identical.

The usual hyaline change was seen in the basophil cells of the anterior lobe of the pituitary gland, the posterior lobe of which contained a cyst.

NEUROPATHY AFTER STILBAMID
TREATMENT OF KALA-AZAR

P. J. COLLARD
M.B. Lond., M.R.C.P.
MAJOR, R.A.M.C., NEUROLOGIST AND MEDICAL SPECIALIST

OF MEDICAL DIVI

From the Queen Alexandra Military Hospital, M

KALA-AZAR may be seen in this country among
who have served in endemic areas, for its incu
may be as long as two years. Thus an account
after-effects which we have noted in patients
with diaminostilbene (stilbamidine) may be of int

Neither Adams and Yorke (1939), who first
stilbamidine in kala-azar, nor Kirk and Sati (1940)
any late effects of stilbamidine treatment, but Napi
(1942) found that several months after treatmen
stilbamidine 9 out of 101 patients developed a
nervous sequel, which had already been descri
Napier and Sen Gupta (1942). Sen Gupta (
further described the neuropathy, which by then
been detected in 17 out of 104 cases. It consist
areas of paræsthesiæ and of anæsthesia to light t
and occasionally to pain over the distribution of
trigeminal nerve, with preservation of sense of tem
ture and pressure. In a few cases these symptoms sp
to the neck.

Oastler and Fidler (1946) reported that 2 patients
Sudanese kala-azar treated with stilbamidine had
late in convalescence, from renal, hepatic, and pancr
damage, and that the same solution of stilbami
administered later to dogs, had caused hepatic and
lesions. No such lesions were produced in dogs
freshly prepared solutions of stilbamidine; so it
concluded that the original solution had become
with ageing. These observations were made in
before it was known that stilbamidine became
after exposure to light (Fulton and Yorke 1942, Fu
1943). However, though the freshly prepared solu
produced no significant changes in the liver, kidney
pancreas, lesions were found in the central ner
system of the dogs, associated with clinical signs.

The clinical picture resembled decerebrate rigidity,
macroscopic and microscopic lesions were found
mortem in the central nervous system, most comm
in the thalamus and caudate nucleus but also in
cerebral cortex, subcortical tissue, cerebellum, b
stem, and spinal cord. Microscopically the le
consisted of myelin degeneration and infiltration
polymorphs, small round cells, and erythrocytes.
was no apparent relationship between the degre
nervous damage and the amount of stilbamidine give

with severe anæmia, leucopenia, and splenome
Kala-azar was diagnosed after sternal puncture, and
was transferred to the Queen Alexandra Military I
pital. After a blood-transfusion he was given two cou
of stibamine glucoside ('Neostam') intravenously,
first totalling 2·1 g. and the second 3·2 g., but a
from slight decrease of his fever he showed no impr
ment. He was then given intravenous stilbami
an initial dose of 0·1 g. in fresh solution being follo
by 0·15 g. on alternate days up to a total of 1·4
After the seventh injection the fever subsided and
general condition improved dramatically. A few w
later he was fit to leave hospital convalescent.

Meanwhile there was a steady flow into the hosp
of soldiers with kala-azar from North Africa, Si
and Italy, both fresh cases and patients who had alre
been treated with antimonial drugs without suc
They too were given stilbamidine, and our first imp

were very good. By the end of 1944, however, arming number of patients returning for follow-up iination were being found to have facial symptoms, two relapses occurred (Hargreaves 1947).

ndes (1944) was finding urea-*para*-amido stibinic (urea stibamine) satisfactory in kala-azar in patients ning to England from the Mediterranean, and ral Sir Alexander Biggam obtained this and an drug, urea-*para*-aminophenyl stibinic acid (carbomide), from India. We then stopped using stilbine and substituted these drugs, which have proved ely satisfactory in the treatment of both Mediterin and Indian kala-azar. The average patient iven two courses totalling 3 g. each of daily intraus injections, and as a rule the fever subsided in r three days after the start of treatment.

ea stibamine and carbostibamide were equally ive, but the patients preferred carbostibamide, se the transient symptoms—flushing, cough, nausea, during injection were much less and often absent. mparison with these drugs stilbamidine had been lesome to administer. Because of its tendency to local venous thrombosis at the site of injection as necessary to dissolve it in at least 200 ml. of lled water. Again, the transient symptoms caused h injection of stilbamidine were often severe unless it iven very slowly—generalised flushing with a burning tion, headache, giddiness, palpitation, epigastric pain, ea, and vomiting. One patient developed auricular lation lasting several hours after an injection.

INCIDENCE OF NEUROPATHY

ogether 24 cases of kala-azar had been treated with midine at the Queen Alexandra Military Hospital e the high toxicity of the drug was recognised. further patients had received stilbamidine abroad. of these was an invalid from Italy with prolonged r and leucopenia. We diagnosed brucellosis and to surprise he complained during convalescence of bness and burning in his face and lips. We found a course of stilbamidine had been given to him rically eight months previously. The total dosage n to our patients was 0·6–3·2 g., and we found no tionship between the dose of stilbamidine and the rity of nervous complications.

e have followed up 24 patients for periods up to e years, and 22 have developed evidence of neurohy at intervals ranging from two to eight months after tment. The 2 apparently unaffected patients were ong those who lived too far away to attend for mination but who answered a written questionnaire. other of this group wrote to tell us that he was quite ll and back at his old civilian job but had to attend sychiatric clinic because of a queer feeling in his face. This incidence of the neuropathy in over 90% of our ients is very much higher than the Calcutta figure 16%. Sen Gupta (1943) was careful to point out, ever, that the incidence might be higher than the res indicated, since not all his patients were followed and the 17 who complained of facial symptoms were stly of the more intelligent type.

CLINICAL PICTURE

Symptoms.—The main symptoms were numbness of e face and sometimes the scalp, neck, and chest; resthesiæ in the same areas, varying from pins-and-eedles to a sensation of hot water trickling over the in; hyperæsthesia, shaving, or a light breeze on the ce often causing agonising pain; itching of the eyelids, ith watering of the eyes and sometimes a sticky secreon; and fine twitching of the muscles round the eyes ith frequent blinking.

Signs.—Sensory changes were found over various areas upplied by the fifth cranial nerves and the cervical and upper dorsal sensory roots. The skin over the affected areas sometimes appeared dry and atrophic. The type of sensory loss was fairly constant, consisting of impaired perception of light touch, blunting of pin-prick, and impaired temperature sensation. When these changes were extensive, vibration sense was also lost in some cases over the bridge of the nose and the chin. Occasionally the corneal reflex was depressed, but it was never absent. Deep pressure and pain sensibility, two-point discrimination, and the jaw-jerk were normal in all cases. Fine twitching of the face and eyelids, with lacrimation, were commonly seen, presumably of reflex origin from irritation of the sensory mechanism of the fifth cranial nerve.

These findings differ from those of Napier and Sen Gupta (1942) and Sen Gupta (1943), who reported that perception of light touch and occasionally pain sensation were affected. In a few of their cases the neck was involved as well as the face; in some of our series, as already noted, the sensory changes spread to the chest.

Onset.—The symptoms came on two to eight months after stilbamidine treatment. The first complaint was usually numbness or pins-and-needles over the upper lip and tip of the nose, the patient often noting that he could not feel a cigarette in his mouth. During the next few days, or occasionally weeks, the symptoms would spread to the whole trigeminal area on both sides and sometimes the cervical and dorsal dermatomes.

Course.—The condition usually remains stationary at its maximal extent and severity from eighteen months to two years, after which it gradually improves. Sensation usually returns in the reverse order to that in which loss occurred, but a few patients, whose symptoms started over the third division of the trigeminal nerve, now show residual signs in the first division only. In one case the numbness spread to the neck in the first two weeks but receded after a further week, leaving only facial signs. We have not found any treatment to influence the progress of the condition, but soluble phenobarbitone has given some symptomatic relief to patients with very severe paræsthesiæ. In most of the patients this neuropathy was a very real disability, and there was no difficulty in detecting old stilbamidine cases in the wards by their miserable expression with blinking and tearful eyes.

ILLUSTRATIVE CASES

Case 1.—December, 1943, to February, 1944: stilbamidine, three courses, total 3·08 g.

May, 1944: numbness and paræsthesiæ over forehead, spreading in a few days over whole face, then receding to left forehead and cheek.

October, 1946: persistent symptoms on left side of face, sometimes spreading over whole face for a day. Sensory changes found over right and left trigeminal areas; pain, light touch, and thermal sensation lost in divisions I and II; loss of light-touch sensation only in division III.

Case 2.—March, 1944: stilbamidine 2·25 g.

July, 1944: numbness of lips, spreading in three months over whole face, scalp, neck, and upper chest, with severe paræsthesiæ.

June, 1946: symptoms improving over chest. Loss of pain, light touch, and thermal sensation over right and left trigeminal areas and cervical dermatomes 1–5.

Case 3.—March, 1944: stilbamidine 1·5 g.

November, 1944: pins-and-needles and perverted sensation over face.

June, 1946: symptoms persist; no sensory loss detected.

Case 4.—May to August, 1944: stilbamidine, two courses, total 2·95 g.

November, 1944: perverted sensation over cheeks; light touch very painful. In a month this spread over whole face and forehead.

February, 1945: perverted sensation subsided, but numbness developed.

June, 1946: numbness of forehead and itching of eyelids; findings as in case 1; typical dissociated sensory loss in divisions I and II of trigeminal nerves; loss of light-touch sensation only in division III.

Case 5.—January, 1945: stilbamidine, amount not known, in Italy.

September, 1945: burning sensation in lips, then pins-and-needles with numbness spreading in a few months over face, scalp, neck, and upper chest. Symptoms gradually receded from chest.

June, 1946: loss of pain, light touch, and temperature sensation over right and left trigeminal areas and cervical dermatomes 1–3; vibration sense lost over bridge of nose.

Case 6.—July, 1946: stilbamidine 0·6 g. in another hospital.

October, 1946: numbness of nose and upper lip, with paræsthesiæ, spreading in four days over whole face; loss of pain, light touch, and thermal sensation over right and left trigeminal areas. Ten days later these changes extended down to 3rd cervical dermatome, then receded rapidly.

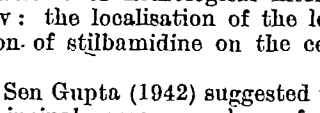
November, 1946: impaired pain and light-touch sensation only over both trigeminal areas.

DISCUSSION

This condition is of neurological interest from two points of view: the localisation of the lesion, and the mode of action of stilbamidine on the central nervous system.

Napier and Sen Gupta (1942) suggested that the lesion was in the principal sensory nucleus of the trigeminal nerve, and Sen Gupta (1943) later postulated that the process might extend caudally into the spinal tract of this nerve and its nucleus. It seems from the more extensive physical signs which we have noted, that stilbamidine may affect not only the principal sensory nucleus and the nucleus of the descending tract of the trigeminal nerve but also the central grey matter of the spinal cord near the substantia gelatinosa Rolandi. The fact that these collections of grey matter form a continuous column of cells which are morphologically similar makes this localisation probable. In the dog stilbamidine has a diffuse effect on the grey matter (Oastler and Fidler 1946), but in man it appears to have a special affinity for this one column of cells. Other examples of specific affinity are known, such as that of trivalent arsenic for the optic nerves and trichlorethylene for cranial-nerve nuclei, particularly the fifth.

The structure of stilbamidine (see figure) is such that it is related to trichlorethylene through its ethylene



linkage, and by reason of its diamidine groups it is akin to diamidino-di-phenoxy-pentane (pentamidine), another synthetic antiprotozoal drug, which is known to cause polyneuritis. Snapper (1947) is using stilbamidine in the treatment of multiple myelomatosis, and during the treatment he has noted specific morphological changes developing in the cytoplasm of the myeloma cells, in which granules of ribonucleic acid appear. His results indicate that in this particular disease the beneficial effects of stilbamidine outweigh its disadvantages.

SUMMARY

Stilbamidine was used in the treatment of Mediterranean kala-azar in 1944, and the results seemed good until an alarming number of patients developed numbness and paræsthesiæ over the face, often spreading to the neck and chest.

These symptoms appeared two to eight months after treatment in over 90% of cases—a much higher figure than the 16% reported from Calcutta, where not all the patients were followed up.

Urea stibamine and carbostibamide were effective in all our subsequent cases of kala-azar, both from the Mediterranean theatre and from India.

The clinical features of the neuropathy are described, with illustrative cases. The symptoms tend to remain at a peak for about 2 years, and then improve grad The nature of the lesions is discussed.

Our grateful acknowledgments are due to Major-Sir Alexander Biggam and Brigadier J. Bennet for thei help and advice, and to the many medical officers who in this work at the Queen Alexandra Military Hospital.

QUARTAN MALARIA TRANSMITTE BLOOD-TRANSFUSION

REPORT OF A CASE

K. B. Rogers
M.B. Lond.
LATELY PATHOLOGIST I/C AREA PATHOLOGICAL LABORA
SHOTLEY BRIDGE

It has been demonstrated repeatedly that h malaria may be transmitted by blood-transfi Thomas et al. (1936), in describing the first case i British literature, emphasised the risk of employi a donor anyone who had resided in a malarious di After the case of Nabarro and Edward (1939), H and Shute (1939) suggested that civilian donors had lived in the tropics or subtropics should not be if other blood-donors were available. Now that so ex-Service men and women are potential donors, may be a tendency for this advice to be disreg The following case emphasises the risk of using d who have visited malarious areas but have not clinical malaria.

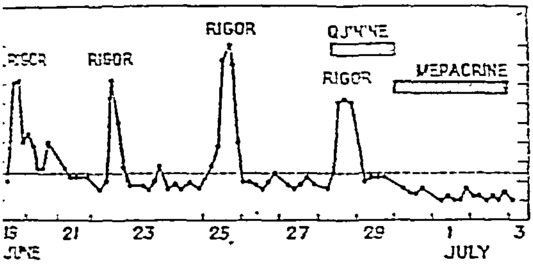
CASE-HISTORY

Mrs. A, a primipara, aged 18, with group-A blood given an antepartum transfusion on March 8, 1946. Sh never travelled outside the Tyne Valley area of Northu land and co. Durham. Her Hb level rose from 40% to after the administration, without reaction, of two pi 3-day-old stored group-A blood. She was discharged, a March 14 returned in labour and was delivered of a full healthy son.

Her puerperium was normal, except that on Mar she had a slightly elevated temperature, interpreted a to constipation, which was treated with suitable aper This was the only pyrexia recorded, and she was disch well on the 24th.

About five or six weeks after her return home, sev eight weeks after the transfusion, she started to fee down. At the same time her sister, with whom she sha bed, refused to sleep with her, because Mrs. A became so with sweat during the night.

The patient was not unwell enough to consult a d before she entered the county postnatal convalescent hor June 15, when she was thought to have a cold. On the she had what must have been a slight rigor; she was the next two days, but had a definite rigor on the 19th, w was repeated, as shown in the temperature chart. She investigated on the 25th, when typical quartan ma parasites were seen in the blood smears; at that tim was pale, with an easily palpable spleen and liver. B count: red cells 3,600,000 per c.mm., Hb 10·5 g. per 100 c white cells 3000 per c.mm. (polymorphs 73%, lympho 23%, mononuclears 1%, eosinophils 3%). Blood-sedim tion rate in 1 hour at 20°C (Wintrobe): patient 53 donor I 9 mm., donor II 5 mm.; corpuscular volume, pa 33 c.cm., donor I 42 c.cm., donor II 40 c.cm.; corrected patient 27 mm., donor I 6 mm., donor II 6 mm. (H and Whitby 1938). Mean corpuscular volume 91 c.μ. corpuscular hæmoglobin concentration 32%. Stained showed normal red cells except for the contained mal



es. Serum did not agglutinate *Br. abortus* emulsion dilutions from 1/25 to 1/2500. Blood-culture proved . Plasma: paler than normal, no icterus present.

nt was treated with quinine gr. 10 t.d.s. for two days en mepacrine gr. 3 t.d.s. for five days; her temperature d remained down after the 28th (see figure) Up to the five months the child has shown no evidence of a al infection.

THE DONORS

r I had been on a cruise which allowed her to land for hours at Algers; no parasites were seen in her blood s.

r II was a ship's engineer who, in 1939, had travelled en, Abadan, and Basra, the trip taking about five. s. He had never had malaria, though several of the ad "3-day malaria" on the voyage back. On his return and in the summer of 1939 he was liable to feel cold uld go to bed for an hour during the day, but he did sult a doctor. Since then he has never been out of d and never had any illness except "flu" during a demic; in a thin smear of his concentrated centrifuged (Rogers 1946) a definite quartan male gametocyte was

d taken from both donors on July 4 was injected into tients with general paralysis of the insane who belonged rd group A. No evidence of malaria has yet appeared patient given the blood of donor I; but the patient the blood of donor II developed malaria on Aug. 5. shown above the sedimentation-rate was not raised in ne who was the active malarial carrier.

DISCUSSION

es of malaria transmitted by blood-transfusion r to be more common in America and France than gland; Wright (1938) added 6 of his cases to make a ted total of 29, of which the only English example was of Thomas et al. (1936). Since then McCulloch (1937), n (1941), Marks (1941), Zussman and Silver (1938), Gardner (1938) have described cases, all of which quartan infections in America; in England rro and Edward's (1939) case has been reported, and s (1946) had another case in a pregnant woman.

e malaria transmitted by donors who have not been nt in malarious areas for many years are nearly quartan infections; but in the cases reported by ier et al. (1934) and Wright (1938) the malaria was n tertian and the donors had carried malaria parasites hree and ten years respectively. Shute (1944) states quartan malaria is *not*, as was once supposed, so h rarer than benign tertian or malignant tertian, ast in some malarious regions; therefore ex-Service onnel who have not had clinical malaria may well as carriers of quartan or benign tertian malaria if l for blood-transfusion. Whitby (1942) stated, and er and Newhouser (1943) demonstrated, that the risk ransmission of malaria by plasma is practically existent.

uggest that all donors who have been resident in arious areas, whether they have had clinical malaria ot, should be bled only for the production of serum. s will prevent the transmission of malaria parasites, and e who have had malaria will be available as safe donors.

SUMMARY

case of quartan malaria, with a long incubation iod, has

It was caused by a blood-transfusion from a donor who had never had clinical malaria and who had lived five months in a malarious area seven years before.

The blood-sedimentation rate was not raised in the malaria carrier.

It is suggested that the blood of donors who have been exposed to possible infection with malaria should be used only for producing serum.

I wish to thank Drs. I. McCracken and E. Ewen for permission to publish this case; Drs. C. B. Bamford, A. L. Banks, T. H. Boon, A. Hart, W. D'A. Maycock, and P. G. Shute, Prof. H. E. Shortt, Miss E. Lowe, Mr. C. H. Holland, and W. Ralph for their help and criticisms.

Medical Societies

MANCHESTER MEDICAL SOCIETY

Lung Abscess

In an address to this society on Oct. 1, Mr. W. F. NICHOLSON said that the common cause of lung abscess is bronchial obstruction with secondary infection. In normal health the cilia lining the bronchial tree keep the air-passages free from organisms and debris. When ciliary action is impaired by trauma, infection, or growth, coughing prevents bronchial obstruction; but when coughing is embarrassed by pain or anæsthesia or tenacious secretion, bronchial obstruction may occur. Abscess due to bronchial embolism arises at the periphery of the lung, though it may not present on the costal surface. Because the subapical segment of the upper lobe and the apical segment of the lower lobe are the most dependent bronchi in the lateral and supine positions respectively, these segments are most frequently affected; consequently, the majority of inhalation abscesses present on the costal surface of the lung corresponding to these segments. Upper-lobe abscess is common after operations on the upper respiratory tract, in which a lateral position is commonly employed during the immediate postoperative period. Lower-lobe abscess is often due to abdominal operations, associated with a supine or Fowler's position. Putrid lung abscess often goes undiagnosed because it is still not widely known that such an abscess can exist without foul sputum. When the abscess ruptures into the bronchial tree, sputum will be present; but even before this happens the breath may be fœtid.

Treatment is by drainage, either bronchial (postural) or external (by operation). In either case localisation of the lesion must be exact if treatment is to be rational. The responsibility of the physician in these cases is heavy: if he delays external drainage the disease may spread to a diffuse suppurative pneumonia of a lobe, which will eventually require lobectomy; moreover, the immediate mortality of conservative treatment is considerable. Only when the physician shares responsibility with the surgeon from the beginning can drainage be instituted promptly if medical measures fail. Chemotherapy and antibiotics, though of value, do not replace drainage. Bronchoscopy is of help in localising the bronchopulmonary segment of the abscess, in improving bronchial drainage, and in excluding the possibility of foreign body or growth: as a curative measure it is little better than postural drainage. Surgical drainage decreases mortality and morbidity.

Reviews of Books

Practical Handbook of Leprosy

R. G. Cochrane, M.D. Glasg., F.R.C.P., medical secretary, Mission to Lepers; principal, Missionary Medical College, Vellore, South India. London: Oxford University Press. 1947. Pp. 283. 42*s*.

For those who have not seen leprosy, or have seen only a few cases, it is often difficult to make a definite diagnosis; and, having made a diagnosis, to classify the type or make a reliable prognosis. To all such, Dr. Cochrane's book will be valuable, especially because of its plates, which vividly illustrate the innumerable forms which leprosy presents. The book relates chiefly to leprosy in India, and particularly in Madras, where the author has gained most of his experience. Atypical forms of leprosy, especially of those found in early childhood, are described in great detail. These forms are the most difficult to understand, and opinion is still much divided about their significance and the best way of classifying them. Dr. Cochrane still places his faith in hydnocarpus oil as the sheet-anchor of treatment in lepromatous leprosy, which is the severe form of the disease; he mentions sulphone treatment only incidentally in a short paragraph. The chapters on the control of treatment, lepra reaction, and the various subsidiary forms of treatment are full and practical. The most important part of the book is perhaps the last section of three chapters dealing with prevention. The methods he has used in the Madras Presidency are given in detail. Not only are the therapeutic measures prescribed, but the social improvement of the people; and this section should be studied carefully by all who seek to launch a campaign against the disease. At the end there are four appendices, giving practical methods of carrying out surveys, and recording the lesions of patients. Unfortunately there are some textual mistakes in the book, and some of the statements will not be very clear to those who are not familiar with leprosy; but on the whole it is beautifully produced.

The Chest

A Handbook of Roentgen Diagnosis. Leo G. Rigler, M.D., professor of radiology, University of Minnesota. Chicago: Year Book Publishers. London: H. K. Lewis. 1946. Pp. 352. 36*s*.

Some of the previous volumes in this series have been an unhappy combination of textbook and atlas. Prof. Leo G. Rigler has made no such mistake, but has produced a really good radiographic atlas of the common lung diseases. There are 338 plates, most of high quality, and the text with each is short and to the point. He assumes that his readers will have some knowledge of radiographic interpretation and a wide knowledge of lung pathology. This book will prove most useful to chest physicians and radiologists.

Jameson and Parkinson's Synopsis of Hygiene (9th ed. London: J. & A. Churchill. 1947. Pp. 791. 28*s*.).—The ninth edition of this outstanding textbook has been prepared by Brigadier G. S. Parkinson assisted by Miss Kathleen M. Shaw, of the London School of Hygiene and Tropical Medicine. Besides giving some picture of the replanned health services, they have considered the regulations made under the Education Act, 1944, rewritten the hospital section, and revised the other chapters in the light of the General Medical Council's new rules for the diploma in public health.

Diabetes and Food Rationing (3rd ed. London: H. K. Lewis. 1947. Pp. 32. 1*s*. 3*d*.).—This is a good clear pamphlet written to help the diabetics attending University College Hospital in their diet difficulties and especially those of food-rationing. It sets out different fixed calorie and carbohydrate levels, giving abundant alternatives. The carbohydrate varies from 150 to 285 grammes; in these days of bread and cereal rationing and potato shortage the latter quantities must be difficult to obtain.

Messrs. Macmillan inform us that in our review of *Human Genetics* by Prof. R. Ruggles Gates (*Lancet*, 1947, i, 911) the price given was that originally announced. Shortly afterwards however this figure was reduced to £3 15*s*.

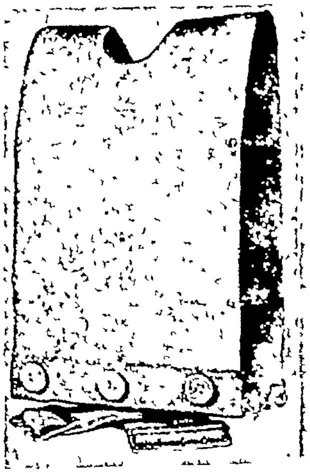
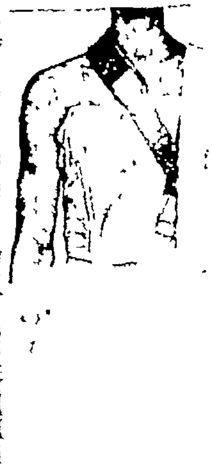
SPLINT FOR FRACTURED CLAVICLE A ACROMIOCLAVICULAR DISLOCATION

Fractures of the clavicle usually unite readil the cosmetic results are often disappointing, methods of splintage commonly adopted, most of are designed to brace the shoulders back, will correct the chief deformities.

The loss of the strut-like action of the allows the shoulder girdle to fall under the gravity and to be drawn inwards by the pull muscles arising from the trunk. Böhler's original splint was designed to correct these two d it has the disadvantage of being rather cl uncomfortable to wear. For some time I using a splint which, while embodying the principles advocated by Böhler, gives the comfort. It consists of a light aluminium fı shaped to fit the chest wall and held against th by a washable corset (fig. 2). The upward lift



1



2

Fig. 1—Aluminium splint.

Fig. 2—Splint applied, with corset and strapping, for clavicular dislocation.

splint is regulated by a strap passing over the shoulder, which should be adjusted so that the a shoulder is above the level of its fellow. To avoid pressure on the axillary neurovascular bundle the border of the splint must be generously padded thick layer of splint wool, which is placed ben flap of the corset covering the top of the splint.

This splint is not only effective in correcti depression of the shoulder but also acts as a in the axilla and restores the width. With the s position pain at the fracture site is abolished a patient can dress and move the arm at the s freely. In most cases the fragments fall into satis alignment; but, when the fracture is transver the clavicle displaced, it may be difficult to accurate apposition.

The treatment of dislocations of the acromiocla joint, which are notoriously difficult to reduc strapping placed over the shoulder and round the is simplified by the use of this splint. The shou first lifted up to the dislocated clavicle; then by turns of 'Elastoplast' over the point of the s (previously padded with adhesive felt) and bel splint (fig. 2) the distal end of the clavicle held firmly against the acromion. The splint worn for 6–8 weeks according to the severity dislocation, but the shoulder-joint can be exercised throughout.

The splint and corset have been made for me by Masters & Son, 240, New Kent Road, London, S.E.1

Protein-replacement therapy

HEPOVITE

A dry granular preparation of malt and enzyme-hydrolysed liver protein, rich in *natural* vitamins and essential amino-acids.

COMPOSITION

(Each 30 grammes contains)

'rotein" (N x 6.25)	15 grm
rbohydrate (Maltose)	11.4 grm
tamin A	500 i.u.
tamin D	50 i.u.
ieurine HCl	1.0 mg
boflavin	2.0 mg
cotinic acid	6.5 mg
ntothenic acid	11.3 mg
ridoxine	0.32 mg
otin	0.065 mg
lic acid	0.05 mg
ositol	8.1 mg

holine, Calcium, Phosphorus and Iron are also present.

DOSAGE

¼ oz. (7 grms) three times daily is sufficient to provide the necessary protein supplement. Hepovite can be taken on a spoon, sprinkled on food or dissolved in milk, fruit-juices or soda-water.

INDICATIONS

To restore and maintain the nitrogen balance in the presence of tissue destruction and repair, e.g. burns, injuries and post-operative states. To provide a dietary supplement in all cases of nutritional deficiency, pregnancy, peptic ulcer, ulcerative colitis and the toxæmias of pregnancy.

Hepovite is issued in tins of 5 oz. at 9/-★ each. Further details on application to the Home Medical Department, Speke, Liverpool, 19, or 50, Bartholomew Close, London, E.C.1

★ *Prices apply to Gt. Britain and N. Ireland only and are subject to professional discount*

Vitamin Therapy—its uses and limitations

ACUTE INFECTIONS

A multiple vitamin supplement is a useful basal treatment in febrile conditions when the requirements for the water soluble factors are increased and the diet is usually restricted.

Some acute infections, moreover, are commonly associated with low body reserves of certain vitamins. Some also, like pneumonia, provide the uncommon example of urinary excretion of vitamin A, following upon functional hepatic disturbance.

For supplying the increased needs of vitamins A, B_1 and C, together with other important nutritional factors, Complevite is recommended for routine use.

COMPLEVITE

A *single* supplement for *multiple* deficiencies

The recommended adult daily dose provides :—

vitamin A ..	2,000 i.u.	vitamin C ..	20 mg.	iodine	not less than 10 p.p.m each
vitamin D ..	300 i.u.	calcium ..	160 mg.	manganese	
vitamin B_1 ..	0.6 mg.	iron	68 mg.	copper

ormation Offices in the New Service

of the faults of the present system of medical ias been that although almost every form of ient is obtainable, somewhere or somehow, it een nobody's business to know where or how. pecial hospital, clinic, or unit has dealt faith- vith the patients who come to it but has been no obligation to advertise its functions, let to see that everyone who might benefit from its ions does so. Exceptions, of course, are the of the health authorities—infant welfare, ulosis, venereal diseases, and so on—which do make their functions known to the public. new service a doctor will be free to prescribe reatment he thinks necessary for his patients; ver, he will be able to demand it of the service whole. The regional boards must therefore what treatment is available for the patients in regions, and there must be some simple and way of handing this information on to doctors sk for it.

advent of the National Health Service will ably lead to much reorganisation of the present haphazard pattern, and each step is bound to the existing arrangements with which doctors become familiar. Some small hospitals will sorbed by big ones; some will be upgraded and the reverse. No doubt doctors will be kept ied of relevant changes by circulars and the like, hey cannot hope to keep every alteration or ation in their heads or even in their files. Then are the everyday problems of practice which so much of the busy doctor's time. Perhaps ient is having outpatient treatment at a hospital arwickshire and is going to London for a few on business; his doctor will want to tell him iost convenient London hospital which will ue the treatment and when its outpatient ns are. Then there are the questions about lescent homes, about scarce drugs or equip- about the help that voluntary organisations ffer in a specific case—questions perhaps that stumped even the hospital almoner. If Thomas can tell an inquirer what hotels are suitable for eeds at the other end of England, and at what surely the same can be done with hospitals, s, and the many auxiliary services of which dical system is built?

ere is a need, then, for information offices— ps one in each region, since many of the questions red will refer to local matters. It would be ble to run such an office with a purely lay staff, n indexing system, built up as knowledge is red and kept accurate and up to date by constant ion, should provide the answers to most of the or's likely questions and should tell the intelligent ator where to apply for more out-of-the-way mation. A lay staff, moreover, will not succumb e of the temptations which beset such bureaux— of giving professional advice on insufficient data. It might be advisable to combine the regional information office with some kind of emergency bed service, so that in urgent cases the doctor, having been told where his patients can be sent, could make arrangements for their transport and admission. In London it would be simple to graft an information office on the existing E.B.S. of the King's Fund, and the experience so gained would be invaluable to other regions considering a similar symbiosis.

Homologous Serum Hepatitis

TEN years ago it was noted [1] that a high proportion of the recipients of two batches of pooled human serum used as measles prophylactic had developed jaundice about two months afterwards; 9 of the cases were fatal. In the same year there were some cases of jaundice developing a similar time after the patients had received yellow-fever vaccine containing human serum, and the jaundice in this group was shown not to be due to infection with yellow-fever virus.[2] It seemed likely that there was some hepatotoxic substance in human serum causing the jaundice. Attention was drawn to the fact that the "staggers," described in 1919 by THEILER [3] in horses immunised against horse-sickness, resembled the serum jaundice in man. A somewhat similar condition appeared in the U.S.A. in 1937 in horses injected with immune horse-serum, either alone or together with equine encephalomyelitis virus vaccine,[4] and in Scotland in 1938 when horses had been injected with an immune horse-serum in an attempt to prevent grass-sickness.

Summing up the position in 1938, FINDLAY and MACCALLUM [5] noted that in every case the inoculum contained homologous substances, either in the form of homologous serum or homologous tissue suspensions. It was possible that the jaundice was the result of hypersensitivity to some constituent of the homologous serum, but anaphylactic effects rarely involve the liver and it was difficult to make out what constituent of the homologous serum could be responsible for a hypersensitivity phenomenon. Other suggestions were that some apparently normal sera might contain an hepatic antibody which damages liver cells, or that a hypothetical virus was present in the serum of some apparently normal human and horse-sera. A year later FINDLAY and his colleagues [6] decided that the most satisfactory explanation of the jaundice following yellow-fever vaccination was that the agent of infective hepatitis had been present in the apparently normal human serum used in the preparation of the icterogenic vaccine. From 1940 onwards there were innumerable reports of this kind of delayed jaundice following the injection of pooled adult serum or plasma, samples of whole blood, or certain batches of yellow-fever vaccine containing apparently normal human serum. In 1943 medical officers of the Ministry of Health prepared a memorandum [7] in which they collected all known incidents of jaundice following the use of homologous blood products; serum was the only definitely proved source, so they adopted the term "homologous serum jaundice" to cover the whole group.

---

[1] Propert, S. A. *Brit. med. J.* 1938, ii, 677.
[2] Findlay, G. M., MacCallum, F. O. *Trans. R. Soc. trop. Med. Hyg.* 1937, 31, 297.
[3] Theiler, A. *Rep. vet. Res. S. Afr.* 1919, 5, 7.
[4] Marsh, H. *J. Amer. vet. med. Ass.* 1937, 91 (n.s. 44), 88.
[5] Findlay, G. M., MacCallum, F. O. *Proc. R. Soc. Med.* 1938, 31, 799.
[6] Findlay, G. M., MacCallum, F. O., Murgatroyd, F. *Trans. R. Soc. trop. Med. Hyg.* 1939, 32, 575.
[7] *Lancet*, 1943, i, 83.

Thus homologous serum jaundice gradually came to be recognised as a definite entity associated with the injection of an agent, probably a virus, present in the serum of apparently normal people, and the term has served its purpose. However, since it has become recognised that the agent may be present in plasma or whole blood and *not only* in the serum fraction, the name is somewhat misleading, as Dr. ASHER points out in his letter in this issue. There have been cases, even recently, where pathologists and clinicians have not considered the possibility of homologous serum jaundice because the patient had received only plasma. With the further recognition of subicteric cases, as in infective hepatitis, it is clear that "hepatitis" should replace "jaundice." Is it time that "homologous serum" also gave place to something more correctly descriptive? FINDLAY[8] has recently suggested "*hæmatic* jaundice (hepatitis) of (*a*) human or (*b*) bovine origin." To many, this term may suggest an association with only the red blood-cells. "Hæmatogenous hepatitis" has been proposed as a better all-embracing title, but if one accepts the results of the transmission experiments in human volunteers done in various countries during the war years, there must be at least two distinct hepatitis viruses, one causing most of the epidemic infective hepatitis and the other most of the "homologous serum hepatitis." It is difficult to conceive how "homologous serum hepatitis" could be kept going among populations by inoculation alone, and we have also the suggestive evidence of FINDLAY and MARTIN[9] and of MACCALLUM,[10] that the virus may be present in the nasopharynx at some stages of the incubation period or early in the disease. In epidemic infective hepatitis we know the virus is also circulating in the blood-stream in the preicteric period when a donor may provide blood and cause "hæmatogenous hepatitis." MACCALLUM suggests that the viruses responsible for the two forms of hepatitis should be called hepatitis viruses A and B, and this seems a satisfactory way out of the difficulties. Whether these are distinct organisms or two strains of the same organism remains uncertain. There is some evidence that infection with virus B actually increases susceptibility to virus A, and it seems that a large proportion of adults in Great Britain are susceptible to virus B whereas there is a widespread immunity, in the adult population, to virus A.

A New Way with Poverty

THE poor-law stood us in good stead; according to G. M. TREVELYAN,[11] it probably spared us the equivalent of the French Revolution. No such regiment of beggars as swarmed in the streets of French towns under Louis XIV was seen in England after Tudor times: "the poor-law was meant to prevent them, and did prevent them by the only practical method, the relief of distress and the provision of work." Even the 1834 Act, which brought its own abuses, contained, as TREVELYAN says, the seeds of its own reform, and must be counted among the forbears of the new National Assistance Bill, the of which was issued last week. Its parents, however, were the Local Government 1929 and the Beveridge report; and we may some pride in the fact that the final stage of t that report into laws is being taken before it is years-old. Public opinion has turned in a new tion during the past century; and the chief between the legislators who planned the 1834 Act those who drafted the new Bill is to be found modern respect for the personal liberty of the Its fundamental aim, explained in a white-pa "to achieve the final break-up of the poor-l create entirely new services founded on conceptions of social welfare." These into two main parts. The relief of destitutio pass out of the hands of the local auth those of a National Assistance Board, financ the Exchequer, which will administer a State for all needy people who are outside the insurance scheme, or whose necessities are not relieved in other ways. To the local author however, remains the task of providing reside accommodation for the old and infirm, and people who need care and attention.

The only qualification for national assistance be "need"—to be defined according to ge standards in regulations approved by Parlia Anyone over the age of 16 who is in need wi able to apply for assistance, and if the nee established he and his dependants will be he There will be no household means test: the reso of applicants will be considered jointly with the their wives and husbands, but no account wi taken of the income of earning sons and daugh though they will be assumed to be making an a priate contribution to the rent and household expe This shows a new respect for the kin of the who—whether grandfather, father, grandmo mother, husband, or child—have been required Elizabeth's Act of 1601 to maintain (if their m allowed) any old, blind, lame, or impotent perso duty which must have kept many an old person resting and young from marrying. The only liabi now recognised are that of a husband to keep wife and children and of a wife to keep her hus and children. The local officers who will deal applications will be the relieving officers under a name, for the same duties of giving emergency by night or day will fall to them. From their decis there will be right of appeal.

It is assumed that few of those seeking assist will be able-bodied persons of working age; but such who decline or neglect to maintain themse or their families may be refused help unless attend a course of training or instruction, or to a re-establishment centre. Tramps and vagran according to the *Times*, there were only about at the last count—may also attend such centres, local authorities will be required to house them porarily in reception centres. The National Assist Board will be responsible for providing means by wh people without a settled way of living "may influenced" to lead a more settled life; but thi a very different approach from that of the old p

12. Summary of the Provisions of the National Assistance *Cmd. 7428.* H.M. Stationery Office. Pp. 12. *3d.*

under which, TREVELYAN tells us, "the personal rty of the poor was not a thing of which much unt was taken"; and the only influences brought ear on the idler, the unemployable, or the drunkard the house of correction or the stocks.

ome of the most interesting provisions relate to care of old people. The county and county- ugh councils in England and Wales, and the nty councils and large burghs in Scotland, are to ide board, lodging, and attendance, and such nities as hot and cold water and laundry services, all who cannot wholly look after themselves. se who can afford it will pay a fixed standard ge for such residential care, and others will pay ast 21s. a week. Those with retirement pensions s a week will thus be able to meet the minimum ge with 5s. pocket-money in hand, and those less will have their income made up to 26s. he National Assistance Board. The principle of ng for residential care is important, for experience he Hill Homes and elsewhere[13] has shown that ment makes all the difference to the self-respect the residents. Local authorities will also be owered to extend to the deaf and the crippled same welfare services as they now provide for blind, arranging, if they wish, for voluntary ies to act as their agents for these purposes.

he numbers needing assistance are at present ller than might be supposed. Since 1946, when ions became payable at rates provided in the ional Insurance Act, the number of applicants assistance has fallen from 1,500,000 to 500,000. ional assistance in its new form will take the ce of unemployment assistance and the granting supplementary pensions to widows and old people w paid by the Assistance Board), domiciliary istance to the blind, and outdoor relief under poor-law (now paid by local authorities), and berculosis treatment allowances (now paid by local thorities at the cost of the Exchequer). It is imated that the numbers transferred to the National sistance Board would be 430,000 people on outdoor ief, 72,000 blind people receiving domiciliary assistance, some 500,000 widows and old people receiving pplementary pensions, and 30,000 people receiving employment or other allowances The National alth Service will take over the 50,000 sick people w in poor-law institutions, and the 18,000 patients mental hospitals; while the 30,000 children prived of a normal home life will come under the ild-care services of the Home Office. The healthy people in the residential homes provided by local thorities will number some 40,000. Under this st heading it is thought that about 20,000 additional ds in residential homes will have to be provided, the course of the next five years, for old people England and Wales, and a further 3000 in Scotland. me 60% of these beds will have to be in new buildings it up with the help of an Exchequer subsidy. As pointed out in the financial memorandum attached the Bill, "the rate at which it will be possible provide these beds in new buildings cannot be reseen," and it is unfortunate that the presentation this Bill should coincide with an embargo on the ilding of houses and institutions of the kind it ll require. If much of the fulfilment therefore lies in the rather distant future we may nevertheless rejoice in a reform which will do much to remove the indignities of poverty. Its realisation will make it easier, without hypocrisy, to see our nation as "a huge team of all sorts and kinds of people."[14]

Annotations

THE PANEL CONFERENCE

THE atmosphere of last week's Panel Conference was very different from that of a year ago. Then, negotiations for the increase in the capitation fee in consonance with the findings of the Spens Committee, had broken down, and war with the Minister of Health seemed imminent. The fiery cross had gone round, and resignations from N.H.I. service had been gathered in every county from almost all panel practitioners. The conference met in a mood of frustration and defiance. Fortunately a last-minute message from the Minister provided grounds for reopening discussions, and a compromise was eventually reached. Satisfaction with this achievement was naturally the keynote of this year's conference; and little criticism arose on the matters reported by the Insurance Acts Committee.

As was to be expected, the delegates demanded up-to-date information about the progress of the negotiations on the National Health Service; and Dr. Guy Dain responded with a statement. Between February and July, he said, detailed discussions had taken place between the Ministry's officers and five subcommittees appointed by the Negotiating Committee; the whole field of controversy had been covered, and no subject excluded from debate. The Negotiating Committee was to meet on Nov. 5 finally to agree on a summarised statement of all the arguments put forward during the discussions. This document was next to be presented to the Minister, who had already agreed to meet the committee on Nov. 11 and 12. The committee's document and the Minister's reply would later be printed and circulated to each member of the profession, and would be the subject of discussion in the British Medical Association's divisions preparatory to the calling of a special representative meeting of the B.M.A. Immediately after this meeting, doctors would be asked by plebiscite whether or not they were willing to take part in the new service.

Having accepted this statement, the conference passed on to discuss points of difficulty already arising in the establishment of the administrative machinery for the new service, in particular the failure of many health authorities to agree to coopt medical men to the health committees to be set up under the 4th schedule of the Act. It agreed to the suggestion of Sheffield that the profession's representatives should press for an amendment of the Act which would make such coöption obligatory rather than permissive. Finally, it asked the chairman of the Insurance Acts Committee, Dr. E. A. Gregg, to speak on the probable future of the I.A.C., the National Insurance Defence Trust, and the Panel Conference itself. Dr. Gregg announced with confidence that though there is no statutory provision for a committee or a conference analogous to the ones that have so long represented doctors under National Health Insurance, the need for them will remain. It will be impossible, he holds, for the new service to be built or maintained without the help of such bodies, and he has no doubt that under one name or another new bodies will arise surprisingly like the old in function and perhaps even in personnel. The conference accepted this prophecy, and proceeded unanimously to elect its present chairman, Dr. J. A. Brown, to be chairman of the first conference to be called after the appointed day.

[14] Sir Stafford Cripps. Broadcast of Nov. 2.

THE THREE R's

Julian Huxley, in his foreword to a UNESCO report on fundamental education,[1] quotes Lincoln's words about the nation half slave and half free being unable to stand, and emphasises that the same applies to a world in which half the people lack the elementary freedom of the ability to read and write. Statistics show that illiteracy reaches vanishing-point in the countries of northern Europe (less than 1%), but in the British Army 20% of recruits during the war were found to be *semi-literate*; Italy, Spain, Portugal, and Bulgaria have illiteracy-rates ranging from 27% to 55%; Asia is fairly constant at 80–90% (except for Japan); and Africa has the highest illiteracy-rate of all, from 90% to 98% among the coloured people. As one might expect, the main features associated with a high rate of illiteracy are mountains and other obstacles, poverty, and over-population.

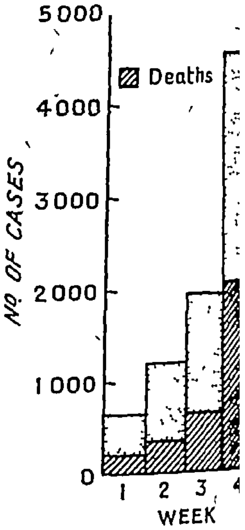
Various attempts have been made by countries all over the world to increase the numbers of those who can read and write. France, for example, uses the French language as a political tool in helping to grant freedom to the native people she rules. In the Union of South Africa, however, the technically trained coloured youth is up against the difficulty that only 1 in 100 stands much chance of getting a skilled job. The fine plans of the Chinese government since 1927 to reduce illiteracy have been upset by the eight years' war against Japan; but even so, the expenditure of some of the district governments on education has been as much as a third of the total budget. In India the chief physical difficulty is that only 15% of people live in towns or cities, compared with 79% in England and 51% in the U.S.A. Lenin's words apply aptly to India: "An illiterate man is outside politics and before he can be brought in he must be taught the alphabet. Without this there can be no politics—only rumours, gossip, tales, superstitions." Often the Indian asks: "Is it worth while for my children to be educated?" and decides in the negative. "Few Indians think education good in itself." Perhaps the most interesting section of the report is that dealing with the attempts of the U.S.S.R. to educate its people; some tribes had not yet emerged from primitive devil-worship and the vast mass were illiterate, though at the other extreme there were small groups of highly educated people. Russian is compulsory in all schools, but education is carried out in ninety different languages throughout the Soviet Union—a remarkable attempt to keep alive the different cultures of a vast land.

The report points out that even in illiterate areas ancient religions such as Islam, Confucianism, and Buddhism have preserved certain forms of education; but these will not serve for today, despite the dangers of uprooting the old ways of life: history provides many examples of civilisations which have snapped from sudden change in their culture. Writing from the standpoint of the anthropologist, Dr. Margaret Mead agrees that such nativistic movements as the American-Indian ghost dance and the revival of Celtic languages may be regarded as expensive drags on the progress of human culture; but she herself seems to disapprove of this view. On the major problem of language the report favours simplification to ease translation from one to another. Sense aids such as films, records, radio, and maps should be used where possible; and emphasis is laid on offering not only the bare bones of literacy in a knowledge of how to read; people should be taught also why they read, and should be helped in deciding what to read.

How far can the West, with its greater power, afford to influence the Orient in fundamental education? Did Britain keep India from sinking through apathy and internecine strife, or will India, with the of Britain's inhibiting influence, raise its living? The report quotes an old African saying: "You Europeans think you have to teach us. If, as you say, we have been eating the food all this time, cultivating our fields and babies the wrong way—why, we'd all be dead. Bu see we are not."

EPIDEMIOLOGY OF CHOLERA

In India upwards of 200,000 die of cholera each and in China the figure is probably larger. This was made by Sir John Taylor at last Monday's of the epidemiology section of the Royal Medicine. Basically, he said, the problem of is the problem of two endemic areas—Lower and the Yangtse valley. There may, however, minor areas of endemicity. From India disseminated by three principal routes. It may via Afghanistan to Persia and south-east Russia; this route has not been followed for many years and it does not appear to be now a major danger. Secondly, it may spread via Iraq and Syria; and Iraq has been infected eight times in the present century. Thirdly, it may spread by the Red Sea to Egypt. The common source of infection in Egypt used to be the annual pilgrimage; this was the cause of the 1902 epidemic when 34,000 died. The pilgrimage was again infected in 1907, 1908, 1911, and 1912. Since then, however, it has not been infected owing to the effectiveness of quarantine measures. Infection is maintained by cases, convalescents, and close contacts; and steps to prevent spread must be re to the infectivity of each of these groups. The incub period may be taken as about five days, so by th route a case infected in India will manifest itself b reaching Suez. Patients excrete the cholera for about five days, though occasionally excretion continue up to thirteen days; close household con excrete the organism usually for about five days, occasionally up to nine days. Convalescents and con will thus be clear by the time that Suez is reac it is unlikely, moreover, that recent convalescents w pass the routine examination at the embarkation p There remains, however, the risk of the missed cas shipboard. With normal air traffic there is no risk of infection being introduced; there have been pected but no proved cases. Positive contacts m however, arrive by air, and the present refugee tr may increase the risk. Even so there is little da that infection introduced into this country w spread.



Cases and deaths in Egypt Sept. 22. A falling inciden reported last week (*Times*, N

Sir Leonard Rogers, F.R.S., prophesied that Egyptian outbreak would now die down though it m come to life again next year. The real danger, he cluded, lies in the Punjab epidemic; for there is g risk that next year it may spread to Russia.

Public-health measures were discussed by Dr. Mel Mackenzie, who said that surveillance was to be imp on air passengers who had spent nights in Egypt.

---

[1] Fundamental Education: Common Ground for All Peoples. UNESCO. H.M. Stationery Office. 1947. 7s. 6d.

ssage took about two weeks, so imported food was oblem. Some countries, he noted, were placing erved confidence in vaccination. For Egypt mass ation, with material made in different countries iffering standards, was a difficult undertaking; ersal standard was required.

P. Bruce White described the work leading up to entification of the three types of cholera vibrio— al, intermediate, and variant. These types were, d, variants of a single species; but though they transmutable, mixed infections were not found. s not absolutely certain that the vibrio was the of cholera: in some epidemics only non-agglutin- ibrios were isolated in about 30% of cases. He een impressed by the consistent absence of labora- nfection. Did the vibrio lose some virulent factor ture?

"CORRECTIVE EXPERIENCE"

r few doctors now deny that more or less expert logical treatment is necessary for some patients: versy has shifted to the choice of method and the solution to the problem created by the cost and ness of psychotherapy. Psycho-analysis, to take lient instance, could never be afforded to the ity of neurotic children and adults (even if it were, ved efficacy in making them healthy) unless me to regard it much as we regard education or ater-supply. Recognition of this dilemma has the one hand to energetic experiments in group ent—taking a leaf out of education's book—and other hand to efforts to shorten psychotherapy it emasculating it. Among psycho-analysts, abbre- or simplified treatment has had short shrift since fection of Adler and Stekel, the ill-starred attempt enczi, and similar misadventures caused anything full" analysis to be classified with hypnosis, sion, and other—more or less despised—alterna- o the rigorous analytic procedure. An enterprising of analysts at Chicago led by Dr. Alexander have years had the courage to challenge this, and their oint and achievements are clearly stated in a ive report.[1] Its keyword is "flexibility": so so, that at the end of his introduction Dr. Alexander oundly that few if any cases require strict adherence ndard psycho-analytic technique throughout their of treatment. He attacks as doctrinaire and ul the standard assumptions about the importance antile happenings in determining later neurosis, e orthodox refusal of analysts to advise the patient his daily life. Psycho-analytic treatment has imes been unjustifiably prolonged, he holds, and ews have been too frequent; too much emphasis een laid on recovery of forgotten memories, which essential to recovery—"merely remembering an dating or demoralising event does not change the of such an experience, only a corrective experience ndo the effect of the old. This new corrective ence may be supplied by the transference relation- by new experiences of life, or by both."

h challenges to widespread psycho-analytic practice theory would have little weight with orthodox sts unless supported, as they are here, by case- ls and respectable analytic experience. Dr. nder and Dr. French hold, with some justification, their methods are a logical continuation of those ted by Freud's discovery that the "transference" dynamic agent of the curative process. The test od treatment, however, does not lie in historical uity or doctrinal soundness, but in the number of ats who are made well; and on the information given the Chicago psychotherapeutic methods seem to stand this test. The work described is important not only to psycho-analysts but to psychiatrists generally, and especially to those concerned with deciding how the people who need psychotherapy may get it in a National Health Service.

CHEMOTHERAPY OF CANCER

To anyone with experience of malignant disease, it is astonishing to see the melting away and total disappearance of a tumour as the result of X-ray treatment. The figures for cure by radiotherapy of cancer of the breast, cervix, and anterior portion of the tongue, which equal those achieved by surgery, have inspired radiologists and surgeons to investigate the laws governing this destructive capacity and to adapt the physical means to these laws.

That the treatment of cancer by chemical methods is equally worthy of further study was shown by last week's meeting of the Royal Society of Medicine's section of medicine. Prof. Alexander Haddow reminded his listeners that to sceptics attempts at chemotherapy might seem absurd, since the cancer cell was only a modified form of the normal; the malignant cell was stable and there was no real evidence of reversibility. The real difficulty was to overcome the energy barrier between the two states; the difference was not structural. By œstrogens, urethane, and β-chlorethylamine cancer might be controlled or modified, though not cured. It was noteworthy, Professor Haddow said, that the value of these drugs had been appreciated thanks to observation for its own sake in man; their effectiveness would not have been guessed from animal experiment alone.

Mr. E. W. Riches reported that 90% of his cases of prostatic cancer treated with œstrogens showed signs of response: 87% were alive at the end of one year, 29% at the end of two, 19% at the end of three, and 5% at the end of four years. If metastases appeared during treatment, the dose should be increased; side-effects were not an indication for stopping treatment. Dr. Edith Paterson referred to the use of urethane in leukæmia. Its effect, she said, is similar to that of X rays. In myeloid leukæmia the cell-count is reduced and the hæmoglobin increased; and in both myeloid and lymphatic leukæmia cell differentiation appears to be increased. Mr. Eric Boyland, D.SC., urged the need for further trial to establish the dosage of chemotherapeutic agents; it would be wrong to follow blindly the dosage adopted in the original trials. Using β-chlorethylamine for the treatment of the reticuloses, Dr. Jean Watkinson had observed symptomatic improvement only in Hodgkin's disease. Dr. O. H. Warwick spoke of the symptomatic relief obtained by the treatment of bronchogenic carcinoma with nitrogen mustards.

That the interests of the patient must be the first consideration in the choice of treatment—whether by surgery, X rays, medical care alone, or one of the newer drugs—was apparent from each speaker's testimony. One expressed the view that the price, in suffering, for mere palliation may well be too great. Professor Haddow deprecated any attempt at assessment of the value of chemical treatment at this stage, claiming that the observations ought to be pursued for their own sake. It is clear, however, that the œstrogen treatment of prostatic cancer has already justified itself, if only by reducing (as Mr. Riches demonstrated) the alarmingly high mortality in the first year of disease.

B.M.A. NUTRITION INQUIRY

THE council of the British Medical Association has decided to appoint a committee to consider "problems of nutrition in this country, including current nutritional standards." The membership will be announced shortly.

THE CHOLERA EPIDEMIC IN EGYPT

Mode of Spread

SAID ABDOU
M.D. Cairo, D.T.M. & H., D.P.H.
ASSISTANT PROFESSOR OF HYGIENE AND PREVENTIVE MEDICINE, FUAD I UNIVERSITY, CAIRO

El Korein, where the present epidemic of cholera started, is a town in the Sharkieh province (fig. 1) with an area of about 40 sq. kilometres. Its main source of wealth comes from its date-palms, and it draws its water-supply from shallow wells. Its inhabitants number 15,000, to which must be added about 6000 immigrants from all parts of the country, settled there to work in the British camps, and a floating population of about 9000 persons during the date season who stay there two or three months to buy and trade in dates.

Of this floating population very few have remained in the town; the rest ran away in the early days of the cordon and played an important part in disseminating the cholera, especially in Dakahlieh province. Of the settled immigrants working in the British camps, only about a quarter escaped and spread over the country.

There is also a third group of immigrants, formed of Bedouin Arabs coming from the east to collect dates and press them into cakes which they carry back to their home country. These are very few and are not an important element in disseminating cholera in Egypt; nor did they introduce the disease, for they had been dwelling in that area for more than two months before the outbreak.

SPREAD BY DATES

El Korein grows about 250,000 date trees, producing about 12,000 tons of dates. It is the main source of supply of dates to the provinces of Sharkieh, Dakahlieh, and Galoubieh. Much of the harvest had already been sold before the epidemic began, but the rest was not properly taken care of and could thus continue to be sold outside, particularly at the beginning of the epidemic. Date cakes find a market all over the country because they can be kept a long time.

It has been proved in Iraq that the cholera vibrio cannot live in compressed dates, owing to the high concentration of sugar; but it can live on the skin of ripe dates for some time.[1] In fact dates have long been implicated in the transmission of cholera. A
a medical commission sent to investigate the fir
of cholera at El-Salhieh in the 1895 epidemic
"Clinical and bacteriological examination ha
that the disease prevailing at El-Salhieh is a
enteritis due to the overeating of dates and
fish. . . ."[2]

Thus two factors of great importance in the sp
cholera appear to be, first, the settlers, most of
come from Dakahlieh and are connected with the
business, a few coming from the rest of Egypt;
secondly, the dates, which are sold all over Lower
especially in Sharkieh and Dakahlieh. In view
slackness in the first days of the cordon esta

. Fearing they might get spoilt, he sold them at a er of the usual price, thus tempting many fellaheen. laughter fell ill on Oct. 6 with cholera, the first victim disease in the town.

the neighbouring village of Abu Naser the first case red on Oct. 7 (recorded on Oct. 8), and it was proved the patient's father had bought 10 lb. of dates on the ous day from Dekernes. Since the omdeh (mayor) had lden the admittance of strangers some days beforehand, ikely that the dates were the source of infection in this oo.

second case in the same village appeared on Oct. 9. atient had had no contact with the first case, but her nd was also said to have bought dates from Dekernes.

omdeh of Miniet El Nasr, which is in the middle of l Kholi Momen, Mit Timma, El Nazl, and Bagalat, all ich rely on the Miniet El Nasr market for their dates, &c., told us that the cars loaded with dates, finding the to Miniet El Nasr closed, escaped to the other villages.

official records show that the cholera started in Mit na on Oct. 6, in El Nazl on the 7th, and in Mit El Momen, Bagalat, and Miniet El Nasr on the 10th.

he neighbouring villages, which lie near the Nile and buy dates from the region of Damietta, there were very few before Oct. 13. The towns near the Nile, from El Zarka of which exposure occurred through Lake Manzaleh) ansurah, were also either spared or very slightly and recently contaminated.

another group of six closely set villages which rely on lifferent sources for their supplies of dates, the three ied from Dekernes were first affected on Oct. 7 and 8, the remaining three, relying on Sherbin, which gets its from Damietta, had only one case, on Oct. 13.

ese facts throw strong suspicion on the dates of orein, which seem second in importance only to the rs who escaped from that region, and it is the more tunate, therefore, that the dates were not destroyed e outset and were allowed to percolate to other places.

PELLAGRA AND CHOLERA

e importance of these agents should not lead us, ver, to overlook two other factors that may have d to disseminate the epidemic in Dakahlieh, not to ion the general poverty, dirt, and ignorance which not more extensive in Dakahlieh than elsewhere.

e first of these factors is the high absolute humidity akahlieh, which was studied by Dr. Halawany and rted on before the special meeting of the Royal ptian Medical Association.[1]

e second needs some explanation. It is well known gastric acidity plays an important rôle in the ection against cholera, and that many parasitic ses, especially those followed by pellagra, diminish ric acidity. Now these diseases are rife in Dakahlieh, pellagra is very common.

hen I visited some tents in the isolation hospital at orein I was struck by the number of cholera patients ving a pellagrous rash. Time did not allow me, ever, to look for other cases or for latent pellagra. he Dekernes Isolation Hospital many cholera cases pellagra were also seen. In Kafr Abu Naser, where rried out a parasitological survey last year, out of holera patients 4 were pellagrins and 8 had some sitic infestation, bilharzia, &c. In Azazna, where a lar survey had been carried out, the only persons to attacked with cholera up to Oct. 13 were likewise agrous. It may be added that almost every cholera ent was uneducated, and most of them were the ims of malnutrition, poverty, and dirt.

WELLS

he main water-supplies have not up to now played apparent part in the spread of cholera; but the wells ch are in general use in El Korein and in most ages of Sharkieh are mostly shallow and badly conicted, and these have been partly responsible for eading the infection.

hus, in El Malakin, a farm community near El Korein 500 inhabitants, there is a well which supplies the whole population because it is the only one containing soft water. This well is formed of a big mud funnel with an earthenware vessel at its bottom to collect subsoil water. It is said that a woman who escaped from El Korein fainted while washing her clothes there and vomited in the well. Next day 70 people had vomiting and diarrhœa. On the same day (Sept. 29) the medical officer of health filled the well and isolated 11 patients. He isolated a further 17 on the 30th, 6 on Oct. 1, 4 on the 2nd, 2 on the 3rd, and 4 on the 4th. No new cases appeared later—i.e., after about 10% of the population had been affected—so the total was 44 cases, with 22 deaths.

In Almiseed, another village in Sharkieh, a deep well had been bored by the Ministry for Social Affairs but had not yet been used. Six cases appeared between Sept. 24 and 30. On the 30th orders were given to open the new well to the exclusion of the others. Only one case was reported next day, and the village has since remained free.

The health authorities are now showing great activity in boring sanitary wells in Egyptian villages wherever the sweetness of the deep underground water allows it.

ANTI-CHOLERA MEASURES IN EGYPT

FROM A CORRESPONDENT IN EGYPT

THE last occasion on which cholera was epidemic in Egypt was in 1902, when it appeared in a group of pilgrims on their way back from Hedjaz; since then there have been only 5 cases, in 1918. The epidemic which started in July, 1902, declined in October, and by January, 1903, all sporadic cases had ceased. The total number of declared cases in that epidemic was 40,316, with a fatality-rate of 85% (34,595 deaths).

The present epidemic started in Egypt on Sept. 22, at El Korein, a village in the Sharkieh province near the British camps on the western bank of the Suez Canal. On the previous day, 3 cases of suspected "food-poisoning" coming from that locality had been admitted for treatment in the hospital of a neighbouring town.

Though cholera had almost disappeared from Egypt for 45 years, and though this was not the season of the return of pilgrims from Hedjaz, which had been the essential source of most Egyptian cholera epidemics in the past, cholera was suspected by the health officer, and without waiting for bacteriological confirmation all practicable measures were immediately taken to wipe out the epidemic.

All land and river communications were stopped in the affected region, and isolation camps for the patients, disinfection stations, and guard posts to keep watch on the principal water sources were erected in great haste.

Contacts were vaccinated from the stores of cholera vaccine kept in the Egyptian Institute of Serum and Vaccine for the pilgrims who were on their way to the Holy Lands this year. The annual production of vaccine is adjusted to satisfy the needs of three times the number of expected pilgrims, which is usually about 20,000 each year. The British Army also offered help by volunteering to spray the dwellings of the contaminated villages with D.D.T., and by providing the isolation hospitals erected there with sterilised water.

On the second day bacteriological confirmation came, and the Egyptian government immediately allocated for the campaign half a million Egyptian pounds, a sum doubled three weeks later. At the same time it informed all international authorities and banned pilgrimage to prevent spread of the disease to neighbouring countries.

These energetic measures, however, did not prevent the epidemic from spreading sporadically to the neighbouring regions, helped by the poverty, ignorance, and bad hygiene prevailing in the countryside, and by the high rate of absolute humidity this year.

Cairo, Alexandria, and the other big cities, largely escaped infection owing to their better water-supplies and hygienic conditions. Strict measures were taken there for food control, general cleanliness, and to combat flies by D.D.T. sprays from special aeroplanes. These measures were helped by the fact that the urban population is better educated and more coöperative. Only sporadic cases appeared in these cities, and most of them actually came from contaminated areas. In Upper Egypt, also, only scattered cases appeared.

A huge campaign is being carried out to vaccinate the whole population of Egypt, now that the local production of vaccine, in addition to the quantities from England, Switzerland, the U.S.A., Russia, and neighbouring Arabian countries, allows it. Nearly 5 million people have already been vaccinated, most of them with a single dose of 1 ml. (8000 million organisms).

FACTORS IN DISSEMINATION

The scattered distribution of the early cases gave the epidemic the appearance of being mostly a contact epidemic, where carriers and patients play the principal rôle in dissemination, either directly or via flies and food contamination. Fortunately, the repeated examinations of water done so far, and the distribution of cases, have not revealed any grave contamination of the large water-supplies.

The work of Sir Leonard Rogers in India on the relation between cholera epidemics and the degree of absolute humidity, which finds confirmation in the previous Egyptian epidemics, led authorities on the subject at a special meeting of the Royal Egyptian Medical Association, held on Oct. 15, to forecast at least a temporary reduction in new cases by the end of November, when the humidity-rates fall below the minimum necessary for the spread of the disease. A return, however, is feared next May, unless it can be forestalled by the search for carriers in the infected areas and repeated vaccination in good time.

The source of the epidemic is still obscure, and no official statement concerning its discovery has been made in Egypt. But many first-hand observers think they can trace the origin of the infection to Egyptian labourers infected by aeroplanes coming from India to British Army aerodromes, where these labourers work. It seems that some of the first cases were actually engaged in these airfields, which, until Oct. 6, were not under the control of the Egyptian Quarantine Department. There is also a coincidence between the Egyptian epidemic and that which started on Aug. 15, 1947, in the Punjab after its partition between Pakistan and Hindustan and the migration of about 5 million persons that followed it. In support of this view they point to the return from India of British troops who used the Suez Canal region as a quarantine station and remained there with their Indian retinue for two weeks before departing for England. British authorities, however, deny that there is any relation between the present epidemic and their Forces. It has certainly been established that the epidemic is in no way related to pilgrimage.

The number of reported cases, including suspects, from Sept. 23 to Oct. 21 reached 8308 with 3230 deaths (39%).

It is too early to express an opinion on the effect of the newer methods of treatment—most fatal cases were too ill and toxic on admission to hospital for recovery to be possible—but experience with sulphonamides has been on the whole disappointing and rehydration seems to remain the mainstay of treatment. Plasma has been used when the blood-proteins were under 4·5 g. per 100 ml. The value of vaccination seems, however, to be fully confirmed. In the Abu Zaabal prisons, with a population of 3751, 78 cases appeared before vaccination was started (i.e., 5·5 per day); during the vaccination period this fell to 2·4 (12 cases), and then no further cases appeared. In Turah prison, with 8720 inmates, 20 cases appeared before vaccination was commenced and none afterwards. Among the whole population of the prisons in areas (about 12,000), the morbidity fell during vaccination period to half the prevaccination rate, the case-mortality of 30% fell to 0; no new appeared after the sixth day following vaccination.

SCOTTISH REGIONAL HOSPITAL BC

The Secretary of State for Scotland has now hospital boards for the five regions of Scotland were defined last June.[1] He has selected the after consultation with the interests he is requi consult under the Act, including the universities, or tions representing the medical and nursing pro local health authorities, and voluntary hospitals total number in each board varies from 18 A third of the members will retire each year, following list shows the names printed in three (a) those retiring in March, 1950; (b) those re March, 1951; and (c) those retiring in March, 1952 chairmen will hold office till March, 1951. TOXICOLOGY RESEARCH

HE following have been appointed by the Medical
search Council to serve on a new committee to advise
l assist them in the promotion of research in toxico-
y, with particular reference to industrial hazards:

Prof. G. R. Cameron, F.R.C.P., F.R S. (chairman), Prof J. H.
ldum, M.R.C.S., F.R.S.; Dr. Donald Hunter, Mr. F. C.
cIntosh, PH.D.; Dr. E. R. A. Merewether: Prof. R. A.
ers, M.D., F.R S.; Mr. J. Davidson Pratt, B.SC., Dr. J. R.
uire; Mr. J. Walker, D.PHIL.; and Dr. J. M. Barnes
cretary).

For carrying out experimental work within the field
ered by the committee, the council have recently
ablished at the Chemical Defence Experimental
ation at Porton, Wilts, by arrangement with the
nistry of Supply, a new Toxicology Research Unit
der the direction of Dr. J. M. Barnes. For clinical
estigations in this field the council already have their
partment for Research in Industrial Medicine, at the
ndon Hospital, under the direction of Dr. Donald
unter, and their Industrial Medicine Research Unit, at
e Birmingham Accident Hospital, under the direction
Dr. J. R. Squire. In appropriate circumstances,
search in the subject may be promoted by the council
ewhere, either within their own staff organisation or
means of grants to independent workers.

In England Now

A Running Commentary by Peripatetic Correspondents

JOY at the preservation of Parliament is more intense in our part of Sussex than anywhere else. The villages give themselves up to thanksgiving on successive evenings from Nov. 1; and the bonfires, like the fuel shortage, get bigger every year. Through the zeal and devotion of Ronnie and Brian Parks, and the use of their father's tractor for collecting wood, the formerly domestic celebrations in the field next door have now become the chief annual event of the Town Row Social Club, attended by no less than four policemen, with the fire-brigade in the offing.

Town Row means the Valley of the Farms; and from this valley, at dusk last Saturday, the fancy-dressed procession, encouraged by the Wadhurst Town Band, made short musical ascents for refreshment on neighbouring hills, returning occasionally to the lower altitude of the Railway Arms. Eventually, $1^1/_2$ hours late, it arrived at the final scene of operations, headed by Ronnie and (I'm proud to say) our second boy Duncan, home for half-term and bearing a flaming torch. Among the vehicles behind were a decorated timber-tug carrying about 40 children; a curious van, open on both sides to display a household interior with a warming-pan on the wall and a kettle on the hob; and the Guy himself, on a tricycle chassis complete with rear light. Mr. Shinwell? Not at all. Guy Fawkes himself, in period costume, twice life-size, and a very model of sallow black-bearded villainy.

With the aid of Mr. Parks as Master of Ceremonies—a title we pardonably misheard at first as Marquis of Abergavenny—the beacon, a fourteen-foot cube of logs and bracken, burst into flame; while the announcer in Mr. Redman's motor-car burst into appropriate song, which despite his efforts remained a solo. (He was good on packing up our troubles; but somehow the atmosphere of *The Road to the Isles* suffers a bit in Sussex when the original unfamiliar words are replaced by "Oh . . . I titety-itey-titey-itey-I.") As time went on, the vast fire sent sparks hundreds of feet into the air to descend on the new thatch of our Wimpole-street psychologist; but we were asked not to throw fireworks at the band. Little bogus old men danced wildly in the wild flamelight; a rather highly coloured WREN, with H.M.S. *Spiv* on her hat, took a collection for something presumably naval; and a stranger accused our Mrs. Parks of cruelty when she tried to catch and rescue Brian's pet ex-lamb (Mary), which didn't seem to be enjoying itself. She was quite successful, however, in rescuing the Police, who went quietly after her for a Slow One in *the house*. The fireworks (£25, only don't tell the Americans) were terrific; but soon after 10.30 and God Save the King we thought it time to recall our party of seven boys (not all ours really) to break their $6^1/_2$ hours' fast. The youngest, whose proper bed-time is 6.15, said to me: "Can we please go out after tea and pick up the firework cases?" Which proves (to anyone who doesn't know) that in the young and ardent the Internal Clock does not always keep good time.

I am glad to report that the Guy was deemed too good to sacrifice. But it had been an anxious evening for him, and he tottered a bit as he disappeared down the lane, with his rear light still burning.

* * *

Plain medical men attending a chemicopharmacological conference are likely to be a bit bewildered. One we attended a few weeks ago brought home to us sharply the complexity of the basic sciences on which modern therapy rests. Much of this spade-work is unintelligible to those whose instruction in chemistry was merely an incidental of medical training, and badly done at that. Our minds flew back to the tedious lectures by uninspired scientists who regarded the teaching of medical students as an unfortunate necessity. But the time lapse was too great, and the most we could do was to show a somewhat dazed interest in what was going on.

The chemists "hogged" the blackboard, covering it with their hieroglyphs. In the maze-like structures depicted some old and simple friends such as benzene rings and amino groups appeared from time to time, but only as the cornerstones of something incredibly complex. Occasionally the fascination of their subject gripped the drawers and they would pass into a dream world of their own, rubbing out a side-chain here and adding one there, substituting one key element for another in an attempt to perfect their scientific architecture, while their commentary degenerated into a low muttering delirium intelligible only to the initiated in their immediate vicinity—and, I fancy, not always to them.

The pharmacologists were a bit nearer reality, and mercifully left the blackboard largely alone. They told of their guineapigs, rats, dogs, and cats; they described the ingenious devices invented to prove their theories, and they aired other theories which still lacked confirmation, thus prompting little discussions tinged with polite disbelief—for what is more controversial than a pharmacological theory?

The overall impression I gained was that modern chemotherapy is on a very sound footing. Much of the painstaking research may at first sight appear to have little practical application but few things can be better justified. If the inquiring mind is allowed a reasonable freedom, if it is not restricted by soul-destroying routine investigations, and if results are interpreted with proper caution then the opportunities for good are immense.

* * *

Yesterday morning I stepped out of my bath and was standing quite still on the mat, looking at something through the open window, when I was struck suddenly by an agonising pain in the small of my back. As on three out of the four other occasions when this calamity had befallen me, I fell to the floor and lay there helpless; it was half an hour before I could even reach the bell-pull to summon help.

I was rescued by my devoted Swiss maid, Lyddy, who fetched Henri the porter and her two sisters. With Lyddy circling round giving advice, they helped me across the corridor to my room where I was put to bed. Lyddy hovered about the foot of it for a while, then all at once she stopped and pointed an accusing finger at me. "It was the Hexenschuss!" she announced. "The what, Lyddy?" I asked weakly. "The Hexenschuss, sir, *the witch shot*"; and I think a suspicion crossed poor Lyddy's mind, good friends though we are, that if I had really been as nice as she thought this would never have happened.

Could any other name more aptly describe the fiendish suddenness with which these attacks begin? And in these primitive Swiss valleys, where superstition is rife and no peasant dare venture out of his chalet after the Angelus has sounded, witchery seems as reasonable an explanation as the prosaic and controversial prolapsed intervertebral disc.

* * *

In the bad old days before 1939, N.H.I. certificate books were just too sensible and compact for words. "First," "intermediate," and "final" certificates were all in the same book, which could be slipped easily into the pocket. When the need to conserve paper first arose an unexpected and quite inexplicable mitosis occurred; the certificate book became two books, one of which contained only "first" certificates and the other both "intermediate" and "final" certificates. Since the need for economy in paper persists it can only be a matter of time before a second irrational mitosis takes place and the second book divides into two, one containing only "intermediate" and the other only "final" certificates.

We shall then be in the happy position of using three things where one would do. This is what is known as "the increasing complexity of modern civilisation."

* * *

Before I took to medicine my work gave me the chance of making friends with a lot of Eels and Butterflies. There weren't any Spivs then; they were just called Wide Boys (and that wasn't tailor talk). We still meet quite often for a quick one. So the other night, about three hours after I qualified, a rather nice Wide Eel I know rang up to congratulate me: "And now we shall have a doctor of our own," he said. "Would you like to make fifty quid? A girl I know . . ."

Letters to the Editor

SEXUAL ABNORMALITY AND THE LAW

SIR,—The recent proposals of Glover, menti
your annotation last week, together with other
tions for the treatment of sexual delinquents
those of Norwood East and Hubert, are parti
opportune in view of the forthcoming Criminal J
Bill. However strongly one may feel that no sharp
can be drawn to divide sexual from non-sexual
quency, the offender against sexual law is ce
singled out by existing institutions for partic
irrational treatment. Inpatient psychiatric t
based on the type of provision which was first
the Inebriates Act is a manifest advance in dealing
compulsive or persistent antisocial acts; but it is
important that in defining the terms of any such
the number and variety of offences should be r
and sexual practices which are not manifestly ant
excluded.

The residue of ecclesiastical law, and the various
sions of the Vagrancy Act, act irregularly and on
whole unfairly: indecent exposure is a sexual off
and has the benefit of the projected treatment sc
while ink-throwing, hair-cutting, and other less obvi
erotic compulsions presumably have not. In the ab
of new legislation homosexuality by consent bet
adults and in private is punishable on very nearly
same basis as homosexual rape. In fact the consen
party becomes a principal.

It is essential to the proper working of any rem
scheme that the law should be made rational, so that
psychiatrist will be morally justified in upholding i
solution would lie in the reduction of the numb
punishable categories to three: conduct offensiv
public decency, or likely to deprave or alarm oth
sexual assault; and sexual assault or seduction of m
of either sex, involving an extension of the age of co
to males. Those sections of the Offences against
Person Act would be retained which relate indirectl
sexual assault, such as that prohibiting the administr
of drugs with intent to ravish. There is no point of
flict between the sexual psychopath and society w
could not be covered by some such scheme, with
prejudice to the well-being of either. It would have
further merit of recognising the privacy of sexual cond
and terminating, so far as the threat of legal proceed
is concerned, the blackmail of respectable homosex
The constitutional invert who conducts himself dece
is no more a suitable subject for prolonged treatm
than he is for permanent segregation.

It may be argued that public opinion is unready
such a revision of the law, and that to press it now wo
endanger the prospect of improved psychiatric facilit
I doubt that, and I doubt whether coöperation is poss
between independent psychiatry and the courts upon
other basis than a radical change in the law. Whil
may be possible to induce a patient to adapt himsel
customs he feels unreasonable, it is rarely possible
reconcile him to acceptance of a position which is unj

London, S.E.23. ALEX COMFORT

BIOLOGICAL COMPETITION

SIR,—From the facts given in your very interest
and stimulating leading article of Oct. 11 there i
submit, a further tentative conclusion to be drawn.

It is stated that all living things appear to req
certain dietary factors besides actual foods in order
live, and that there is close correspondence between
essential metabolites of bacteria and the vitamins
higher organisms. The work of Kögl[1] and others
plant growth factors (auxins) appears to indicate t
plants too require substances closely corresponding
the essential metabolites of bacteria and fungi,
the vitamins of higher organisms. Kögl isolated ind
3-acetic acid (hetero-auxin) from urine, whilst ot
auxins have been isolated from human urine and
known to be widely distributed in animal and pl
tissues.[2] Compost is prepared from animal excreta

---

1. *J. physiol. Chem.* 1934, 228, 90.
2. *Brit. med. J.* Annotation, 1943, ii, 170.

nt tissues, and fungal and bacterial activity is known be increased during its preparation.

Rowlands and Wilkinson[3] reported rat-feeding experints with grass and clover seeds grown in soils treated the artificial and organic manurial methods. which ıld appear to suggest that vitamin-B factors may l be absorbed directly or indirectly from the soil ıtion by plants grown under organic conditions; in this connexion Rayner's work on the mycorrhizal ciation of plants should not be forgotten.[4]

t is known that natural organic manures contain min-B factors, amino-acids, auxins, and intestinal teria capable of synthesising vitamin-B and other ors. It is believed by many that these manures luce healthier plants of greater nutritional value for nals and man. Is it not time that we of the medical ession paid a little more attention to the work of Soil Association and to their clamouring for more arch on this matter, which may well be of vital ortance to the survival of our civilisation?

itchin. ROBERT WIGGLESWORTH.

REPTOMYCIN IN INFLUENZAL MENINGITIS

IR,—In your issue of Oct. 25 Dr. Gottlieb writes: fluenzal meningitis responds to penicillin in adequate s, as we have recently shown (*Lancet*, Aug. 2, p. 164)." article to which he refers contains reports of 4 cases nfluenzal meningitis treated with penicillin—surely an lequate number on which to base his conclusion.

Vhile there are a number of reports of successful tment of this condition by varying doses of penicillin do not seem to be justified yet in expecting success very case, even with large doses. It may be argued streptomycin should not be exhibited until massive icillin therapy has failed to arrest the infection, thus ing more streptomycin for hæmatogenous forms of erculosis. Even then. however, the condition of the ient might have deteriorated to such an extent that ptomycin might fail.

therefore do not agree with Dr. Gottlieb that ningitis due to *H. influenzæ* should not for the present treated by streptomycin. Those suffering from this ase should have the benefit of a drug which has loubtedly proved highly successful in the United tes, while at the same time the Medical Research ıncil can have the opportunity of comparing results his country with those reported in America.

ockport. C. DOVE CORMAC.

STIMATION OF PREGNANEDIOL IN URINE

IR,—The methods hitherto described for the estima- ı of pregnanediol in human urine are, because of ir lack of sensitivity or specificity, not entirely isfactory for the determination of small amounts reted during the menstrual cycle or the early stages pregnancy. We have recently developed a procedure ed on the methods of Astwood and Jones[5] and of bot, Berman, MacLachlan, and Wolfe[6]; this seems to e certain advantages over previously described thods. Using one-fifth of a 24-hour sample of urine s possible to determine pregnanediol with fair accuracy en this is present in amounts greater than about ng. per 24 hours. Four to six estimations can be npleted in two 8-hour working days, and the cedure is one that can be carried out by a competent oratory technician under supervision.

n the procedure devised by Astwood and Jones and eloped by Talbot and his associates free pregnanediol is racted by toluene from the urine after boiling with acid; l it is purified by treatment of the extract with sodium lroxide to remove acidic substances, and by subsequent cipitation from hot ethanolic solution with four volumes N/10 sodium hydroxide and/or water. This procedure s been modified by us in order to achieve the rigid standisation of technique which is essential if small amounts pregnanediol in the urine are to be estimated with reasonle accuracy. The most important of these modifications concerned with cooling after the hot-precipitation purification procedure; it has been shown that rapid cooling of the precipitation mixtures results in low and irregular recoveries of pregnanediol, while slow controlled cooling regularly gives more exact quantitative recoveries. The accuracy of the method has been tested out by recovery experiments in which pure sodium pregnanediol glucuronidate[7] was added in varying amounts to 24-hour samples of human male urine. Recoveries of about 70–80% and of 90–100% were obtained when 2 mg. and more than 5 mg. of pregnanediol (as the glucuronidate) respectively were added to 24-hour samples of urine. With less than 2 mg. per 24 hours the recoveries were poor.

This method is likely to be of value in quantitative investigations of pregnanediol excretion during the menstrual cycle and in pregnancy. It may also be of some value for the diagnosis of pregnancy, and there is reason to hope that for this purpose it may be less subject to both positive and negative errors than the more rapid procedure of Guterman.[8]

Full experimental details of this work will be published elsewhere. Since, owing to present conditions, publication is likely to be greatly delayed, the authors will be pleased to supply privately full details of the procedure to any workers who may be interested. They regret, however, that they will be unable to supply samples of pregnane-3(α),20α-diol and of sodium pregnanediol glucuronidate for use as standards.

A BOOK REVIEW

SIR,—With reference to the review of my *Diseases of Children's Eyes* in your issue of Sept. 27, I shall not try to deal with the matters in which that writer's opinion on clinical work differs from mine. When the reviewer states, however, that "the influence of maternal rubella in the ætiology of congenital cataract is not mentioned," he is saying what is untrue. The subject is mentioned on p. 54 of the book in question. I submit, Sir, that a reviewer's duty to his professional public should prevent him from making such a statement *unless* he has read the whole of the book which he purports to discuss. Otherwise the obvious retort must be: "What you mean is that the subject was not mentioned in those pages of the book at which you happened to glance."

London, W.1. J. H. DOGGART.

⁂ Mr. Doggart is right in saying that this subject is in fact mentioned on p. 54 of his book, where it receives the following sentence: "It has also been proved that infantile cataract is in many cases due to German measles affecting the mother during pregnancy." This important contemporary discovery is not, however, accorded a place in the sections on Cataract, Diseases of the Lens, or the Development of the Eye; nor do Rubella, Measles, or German Measles figure in the index. Readers turning to the book for information on the association of cataract with rubella might well share our disappointment.—ED. L.

STUDENT HEALTH

SIR,—Your readers may be aware that the British Medical Students' Association has been discussing the problem of student health for the past two years. At the last annual general meeting in London the following resolutions were made:

> "That the B.M.S.A., taking into account the hazards to which clinical students are exposed and bearing in mind the facilities which already exist in all teaching hospitals, views with concern the absence of any compulsory medical examination for clinical students on admission to hospitals. The B.M.S.A., therefore, recommends very strongly that all schools which have not already done so should with the least possible delay arrange for regular compulsory medical examinations for all their clinical students."
>
> "That the B.M.S.A. recommends that every university should appoint a full-time medical officer who, together with such assistance as may be necessary, should be responsible for the routine compulsory medical examination of all

matriculated students with the dual object of raising the standard of student health by giving advice and of obtaining information about the student morbidity-rate and its relationship to the varying factors in university life."

Compulsion was agreed on after considerable discussion because the delegates from all over the country realised that voluntary student-health schemes, where they existed, have left a good deal to be desired. It must be further pointed out that entrance to university will in no way be influenced by medical examination as this will take place after students have already matriculated. It is hoped that the first resolution will be acceptable to many schools in the very near future. The second resolution will be sent on to the National Union of Students and the Scottish Union of Students with the hope of formulating a united student policy on this important problem.

S. M. DRANCZ
Edinburgh. President, B.M.S.A.

SOCIAL MEDICINE

SIR,—In reply to Mr. Bedwell's letter in your issue of Oct. 18, I would like to say how invaluable I have found the help of the district nurses ever since I have been in practice. But I would not dream of wasting a nurse's time on the type of case I outlined in my original letter. Such a case needs no nursing. Welfare of the simplest variety (such as that offered in many instances by the Family Welfare Association) is all that is necessary. It could be supplied by any woman with sound common sense, who has knowledge of local facilities for healthy recreation, and knowledge of how best to help the new arrival from the country to adapt him or herself to the hostel-cum-office life of our big cities.

Once more I would reiterate that I am acutely aware of the necessity of economising our use of our trained welfare and health workers. Any amount of work of the sort I have in mind could be done by voluntary workers, provided trained supervision is organised.

London, S.W.10. A. E. B. HARDING.

GRANULAR PROCTITIS

SIR,—Following Dr. Oluer's article of Aug. 2, we had a request for 3 g. suppositories of succinyl sulphathiazole for treatment of a further case of granular proctitis.

We decided to use a 120-grain pessary mould, which yields a suppository of about $1^3/_8$ in. length and $^3/_4$ in. diameter. In making the suppositories we found that the medicament had a density of about 1·2 compared with oil of theobroma. A good suppository, which set rapidly on cooling, was obtained as follows:

Succinyl sulphathiazole gr. 45.
Cocoa butter gr. 83.

We believe that this method is less laborious than that employed by Mr. Barclay for Dr. Oluer's cases.

Westminster Hospital, KENNETH MACDONALD
London, S.W.1. Deputy Chief Pharmacist.

GAUCHER'S DISEASE WITHOUT SPLENOMEGALY

SIR,—I should like to offer some criticism of Dr. Morgans's article of Oct. 18. In the summary she writes:

> "A family affected by Gaucher's disease, but in whom none of those affected show splenomegaly, is described. The diagnosis was made by the detection of Gaucher cells in the bone-marrow and by the presence of typical radiological lesions in the bones. The family history suggests that in this series the disease was not only congenital and familial but also hereditary."

If we accept case 1 as a case of Gaucher's disease, diagnosed in the absence of splenomegaly on the basis of (1) a myelogram containing 0·4% of Gaucher cells, and (2) radiological translucencies in the bones, then, I suggest, the evidence submitted in regard to the other cases permits of no more than a diagnosis of "familial radiological translucencies"—to misuse the word diagnosis.

Why were not cases 2, 3, and 4, submitted to sternal punctures? We are not told that they refused. Cases 2 and 3 are included as "proved Gaucher's disease," on the basis of radiological translucencies, while case 4 is excluded on a lesser degree of translucency. Case 3 is described as a proved case of Gaucher's disease without splenomegaly, but, we are told, this case was not examined.

The illusory family tree depicts 3 "proved sternal puncture was performed on only 1 of the other 5 cases of "suspected Gaucher's disease" not known whether splenomegaly was present or The diagnosis of Gaucher's disease without sp would be difficult enough to satisfy anyone with standards, and I would suggest that the rem material submitted by Dr. Morgans, though pro with interesting speculations, was grossly in a diagnosis of Gaucher's disease, of the disease in absence of splenomegaly, and as being of an h nature.

West Herts Hospital, G. A. MATTHEWS
Hemel Hempstead. Pathologist, E.P.S.

BRITAIN'S CALORIE REQUIREMENTS

SIR,—In the paper by myself and others Nutrition Society on Oct. 25, it was suggested th pared with pre-war, the consumptions of sugar, fruit, and grain could advantageously be decr 14%, 5%, 1%, and 6% respectively—not stated in your report last week. Only the fi dairy products, potatoes, and vegetables r percentage increases.

Ministry of Health, London, S.W.1. E. R. BRANSB

HOMOLOGOUS SERUM JAUNDICE

SIR,—In your report of the discussion on infec hepatitis at the International Conference of Physic (Sept. 20, p. 435) you say:

> "Dr. F. O. MACCALLUM proposed that the virus gi rise to epidemic hepatitis should be known as 'hepa virus A,' and that giving rise to homologous serum jaun as 'hepatitis virus B.' . . . While with virus A the orga is absent from the nasopharynx and present in the fa urine, and serum, with virus-B infections it is present in nasopharynx and absent from fæces and serum. . ."

Surely the whole point of homologous serum jaun is that it can be transmitted by serum, so that the v must be present in the serum of infected persons.

Incidentally, why cannot the illness be called "serum jaundice"? As soon as a successful ani recipient has been found the term "homologo will lose what little point it had. As it is, we do not "homologous ringworm," even when we catch it fr our own species.

London, W.1. RICHARD ASHER

***We are obliged to Dr. Asher for pointing out this er Terminology is discussed in our leader columns.—ED.

E.B.S. PHONE NO.

SIR,—As from Friday, Nov. 7, the telephone num of the Emergency Bed Service has been changed MONarch 3000.

R. E. PEERS
London, E.C.2. Secretary.

DUE ACKNOWLEDGMENT

SIR,—As deputy chairman of the medical group the Royal Photographic Society, I have been asked the committee to point out to you that although excell reproductions of photographs are published in y journal to illustrate articles, in many instances recognition is given to the photographers concerned the authors. If acknowledgments of this kind could made regularly, my committee feel sure that it would g great encouragement to all medical photographers.

London, S.W.7. H. MANDIWALL

REVOLT FROM THE BEDPAN

SIR,—I was most interested to read in your issue Oct. 4 the article by Professor Bohmansson and Malmros. Messrs. Down Bros. and Mayer & Phe Ltd., made for us a wheel-chair with w.c. seat cop from the Bohmansson chair. This has now been in in one of the male surgical wards in the Royal North Infirmary, Inverness, for over three months; it is great success and is much liked by both patients a nurses. It has all the advantages claimed for it Professor Bohmansson. We have ordered another ch for the corresponding female ward.

Inverness. A. J. C. HAMILTON.

PRESENT STATUS OF DISC SURGERY

R.—Your leading article last week would have been valuable if it had included also "the other side e picture." I have received from America a reprint article by Aitken and Bradford on End Results of ured Intervertebral Discs in Industry (*Amer. J.* March, 1947).

ell written, unassuming, and I believe entirely free bias, this article is a terrible indictment of the sale mutilation of spines that is proceeding at the nt time under the obsession of the prolapsed disc. limsy evidence upon which the diagnosis is made, igh proportion (40%) of cases in which admittedly rolapsed disc has been found at operation, the ss extirpation of perfectly normal discs on the y unwarranted assumption that they were "con-l discs" or discs which pop in and out, the extensive ectomies and the multiple operations that have done in some cases, and the very high proportion) of unsatisfactory end-results are some of the s clearly brought out in this paper. It is noted that cases (170) under review were dealt with by some of most distinguished neurosurgeons and orthopædic eons in America. Lastly, attention is drawn to the that the disc is only a part of the complex articulation een two vertebræ and its destruction leads to a s mechanical disturbance of the articulation as a le. It is therefore becoming increasingly evident t in many cases, if not in all, spinal fusion should be rt of the operation for a prolapsed disc. Why it ld be considered necessary for one surgeon to ove a disc, and for another to do a fusion, I have er been able to understand. Hitherto affections of spinal column have always been within the province thopædic surgery.

o-one today doubts that the prolapsed intervertebral is a genuine pathological lesion. There is reason to eve that a disc normally exists under considerable tive pressure, and when it is ruptured part of it is ruded under pressure into the spinal canal. Here it ns a lump which is likely to press upon a nerve-root d cause sciatic pain. When such a lump is present, it be found and removed by operation; when no such np is present, the diagnosis is wrong and it is quite xcusable to "explore" a disc by thrusting a blunt trument into it and scooping it out.

For centuries sciatica has been known to be mainly affection of middle-aged and elderly people, most of om have osteo-arthritis of the lumbar spine and are ble to attacks of "lumbago." Rupture of a disc is accident which happens in comparatively young ople under stress or strain. It may cause sciatica ther directly by pressing on a nerve-root or indirectly leading to (traumatic) arthritis of the lateral joints. ordinary peace-time conditions the prolapsed disc is obably the direct cause of sciatica in about 4–5% of es. (This was the figure given by Grafton Love when presented his first series of 300 cases from the Mayo nic.)

To say that practically every painful back is due to a olapsed disc is fantastic. Carried to its logical conclusion means that practically every adult human being has prolapsed disc, for there are few of us who have not at me time or other had a pain in the back.

To say that the majority of cases respond to conservave treatment and that only a small proportion of them quire operation is begging the question. Without peration there is no proof whatever that these cases ave prolapsed discs.

The reduction or replacement of a prolapsed disc by anipulation is I believe pure imagination, contrary to ll probability, and unproven. Like the "small bone out f place" of the bonesetter it may serve as a pretext r manipulation, and there are many painful conditions f the back which can be relieved by manipulation and hysiotherapy. But no-one who has seen a disc forcibly xtruded into the spinal canal is likely to believe in anipulative reduction.

Unquestionably the correct treatment for a prolapsed sc is to remove it. But it would be a thousand pities this most valuable contribution to surgery were to become discredited by "an enthusiasm which in some instances has largely replaced common sense."

In lighter vein, but still seriously, I would protest against the suggestion of removing snails from the spine! As an example of illiterate jargon surely it would be hard to beat "excochleation of disc herniation" (*J. int. Coll. Surg.* 1946, 9, 531).

London, W.1. A. S. BLUNDELL BANKART.

Parliament

FROM THE PRESS GALLERY

Medical Practitioners and Pharmacists Bill

IN the House of Lords on Oct. 28, Lord HENDERSON introduced this Bill, whose primary purpose is to dispose finally of the various war-time problems associated with admission to the Temporary Register of doctors holding colonial or foreign qualifications. As already explained (*Lancet*, Aug. 9, p. 225; Aug. 16, p. 250) it empowers the General Medical Council to grant permanent registration (1) to doctors whose temporary registration is due to terminate at the end of this year; (2) to doctors now resident in this country who served overseas with H.M. Forces and therefore had no occasion to seek registration; and (3) to other doctors whose presence here is due to the war and who could not equitably be expected to take a British diploma. Doctors in the first two categories will have to satisfy the council that they have rendered satisfactory service in a medical capacity while temporarily registered or while serving in the Forces; and those in the third category (whose registration will be provisional for 6–18 months) must show that they are of good character and that they have been selected for medical employment in a hospital or institution approved by the Health Departments for this purpose. The Bill also seeks to regularise the position of doctors from abroad who are making temporary visits to hospitals in this country—either eminent practitioners, invited to give demonstrations, or doctors coming for postgraduate study. These will be eligible for registration while working in a hospital approved by the council.

Arrangements are proposed for registration of pharmacists holding qualifications granted outside the United Kingdom.

Local Government Bill

This Bill, presented to Parliament on Oct. 27, provides for a new system of financial assistance from the Exchequer to local authorities in England and Wales. The Ministry of Health's assumption of responsibility for hospital services, and the termination of the poor-law (see p. 692), will relieve local authorities of expenditure estimated at £63 million annually. Instead of the "block" and "supplementary" grants they now receive from the Exchequer, county and county-borough councils will get "equalisation" grants if their financial resources do not reach a certain minimum based on the average rateable value per head of weighted population. If these equalisation grants had been given in 1946–47 they would have amounted to about £33 million, which is £24 million less than the local authorities received in block and supplementary grants; but with a saving of £63 million there would be a gain of about £39 million. It is estimated that in 1946–47, 54 of the 61 administrative counties and 55 of the 83 county boroughs would have qualified for an equalisation grant.

Valuation for rates, at present a function of the local authorities, is to be undertaken by valuation officers of the Board of Inland Revenue, and a new procedure for the valuation of dwelling-houses is laid down. The first revision of current lists is to be completed by 1952 or 1953.

QUESTION TIME

Scientific and Technical Periodicals

Mr. F. J. ERROLL asked the President of the Board of Trade, in view of the urgent need to disseminate scientific and technical information in Britain, when he will increase the domestic paper ration for scientific and technical periodicals.—Mr. HAROLD WILSON replied: Steps are being taken to ensure to journals devoted primarily to original research their full requirements, and I hope to exempt technical periodicals from the reduction which it is necessary to make in the paper available for periodicals generally. Mr. ERROLL: Will the Minister take immediate steps with regard to the British publication *Nature*, as more copies of that publication are now available to Russian scientists than to British scientists? Mr. WILSON: I will take a look at that.—Mr. WILSON HARRIS: Could the Minister say how a technical periodical can be defined and how a non-technical periodical can make itself sufficiently technical to qualify to the increased ration?

Import of Scientific Books

Mr. N. H. LEVER asked the President of the Board of Trade if he would state the average annual expenditure in respect of the period 1940–45 upon non-fiction books imported from the U.S.A.; the amount spent in 1947 during the free period; and the estimated dollar saving expected from the recent restrictions placed upon the importation of such books.—Mr. WILSON: The value of imports in 1940–45 averaged some £170,000, and the value from Jan. 1 to Sept. 11, 1947, when the Open General Licence was revoked, was £720,000. The monthly rate of imports was increasing and it is estimated that an annual saving of nearly $5 million will result from the restrictions now imposed.

Mr. LEVER: Is the Minister satisfied that this cut will not adversely affect scientific and medical research, particularly having regard to the shortage of paper and the resulting shortage of technical books and the like in this country at present?—Mr. WILSON: We are arranging for imports of non-fiction to come in up to the rate of 100% by value of pre-war imports. I recognise that is not 100% in volume, but this new change has only recently been made. We are watching the position and if we see evidence that essential books are being kept out, we will certainly look into the matter again.

Deaf-aids

Mr. ERROLL asked the Minister of Health why, in view of the fact that 80% of deaf-aids now manufactured were one-piece aids, he had decided on a two-piece aid for free supply to the deaf under the National Health Service.—Mr. A. BEVAN replied: The decision has been taken owing to the disproportionate cost involved in using the miniature batteries required for one-piece aids.—Mr. ERROLL: In view of the fact that the Government aid is being manufactured on a mass-production basis surely it is possible to make a one-piece aid on a cheaper basis?—Mr. BEVAN: My technical advice is to the contrary. Replying to a further question Mr. Bevan said the aids would be available when the National Health Service started on July 5 next year.

Mr. ERROLL: What scale of spares and replacements had been allowed to service the aid?—Mr. BEVAN: The general basis adopted has been an annual replacement rate of 25% with a higher rate for valves owing to their shorter life.—Mr. ERROLL: Can the Minister say why a very much higher rate of replacement was decided upon in the case of this unit than is customary in normal commercial practice? Mr. BEVAN: I understood that British valves are being used in order to save dollars and we could not be sure what the experience with them will turn out to be.—Mr. ERROLL: Has not the instrument been properly tested?—Mr. BEVAN: Certainly.

Closing of Wards

Mr. C. OSBORNE asked the Minister of Health how many hospital wards had had to be closed for the lack of staff; how many hospitals were affected and what part of the country was most seriously affected; what was the cause of this situation; and how he proposed to overcome it.—Mr. BEVAN: My information is that at the end of June, there were over 50,000 beds closed for lack of staff. The hospitals were situated in most parts of England and Wales, though more in the populous counties. Causes and possible remedies have recently been examined in the report of the Working Party on the Recruitment and Training of Nurses.

Mr. ERNEST THURTLE asked the Minister if he had considered the memorandum signed by 33 medical practitioners in Shoreditch and neighbourhood regarding the threatened closing of the inpatient wards of St. Leonard's Hospital, Shoreditch, and asking that he should intervene and cause a public inquiry to take place before action to close the hospital is taken; and what action he was taking.—Mr. BEVAN replied: The London County Council have appealed to me under the Nurses Registration Act, 1919, against the decision of the General Nursing Council to withdraw tion from this hospital as a training school for am arranging for the appeal to be heard Mr. THURTLE: Will the Minister bear in mind that people in this area to whom this hospital is a great are looking for him to maintain a firm front General Nursing Council on this matter?—Mr. I will certainly take all relevant considerations into including the General Nursing Council.

Closure of Nurses' Training Schools

Mr. S. HASTINGS asked the Minister of Health how the 24 hospitals from which recognition as training for nurses has been withdrawn by the General Council and how many of the 37 hospitals from withdrawal is proposed, are municipal and how voluntary.—Mr. BEVAN replied: Of the 24, 23 are vo and 1 municipal, and of the 37, 25 are voluntary municipal.

Mass-radiography Sets

Replying to a question Mr. BEVAN stated that 23 mass-radiography sets operating in England and Arrangements were in progress for starting 14 mo further expansion was planned as apparatus comes Up to the end of June 1,669,000 persons had been

Calorific Value of Prison Diet

In answer to a question, Mr. CHUTER EDE stated 1938 the diet for men in prisons contained 2094–4200 per diem, and for women 2542–2901 calories, depen the form of labour at which the prisoners were e and the length of their sentence. At Borstal inst for boys the diet contained 3775 calories per diem, girls 2669 calories. In 1947 the diet for male p contained 2923–2955 calories per diem and for wome 2605. The diet for male young prisoners containe 3051 calories and for female young prisoners 25 calories per diem. At Borstal institutions for boys contained 3261–3389 calories per diem, and for girl 3223 calories.

Anti-cholera Measures in Suez Canal Zon

Mr. HASTINGS asked the Secretary of State f what precautions were being taken to prevent the s cholera to H.M. Forces stationed in Egypt.—Mr. E. S replied: Stringent preventive measures are being t ensure that food and drink are free from contam Native villages and restaurants have been placed bounds, and anti-fly measures have been intensified. A has been drawn to the necessity for a high standard of hygiene. Wholesale anti-cholera inoculation has not found necessary, but all men at special risk and tho to come in contact with infected material or to pass infected areas are inoculated. The question of ino all troops in Egypt is kept constantly under review an the situation deteriorate this additional measure adopted at once. In the meantime inoculation is not to any who desire it, whether or not they are at specia

Calorific Value of Rationed Foods

Mr. E. P. SMITH asked the Minister of Food the value of the daily food of an adult in Great Britain r in terms of rationed and point foodstuffs.—Dr. E. S SKILL replied: The caloric value of the rations, in points rationed foods of the ordinary adult, is abo calories per day.

Milk Ration for Babies

Mr. Q. HOGG asked the Minister of Food why he ha it necessary to cut the babies' milk ration.—Mr. J. St replied: The milk allowance for babies up to 12 old has not been reduced. The reduction in the al to children between 1 and 5 years of age was n preference to reducing other priority or non-priority all on the recommendations of our medical and nut advisers.

Meat for Canteens

Sir WILLIAM DARLING asked the Minister if he reconsider the 2½*d.* per meal meat allowance to in canteens as compared with the civilian ration allow 1*s.* per week; and what action he proposed to tak STRACHEY replied: The meat allowances to all canteo recently cut in common with the domestic ration. I propose to make any alteration in the ratio between all to industrial canteens and those to other establishm

Public Health

Manchester's Water Shortage

Nov. 3 the Manchester waterworks committee d that the water-supply to domestic premises in ester and in 25 neighbouring towns must be cut n Nov. 11 till the service reservoirs at Longdendale harged. The *Manchester Guardian* of Nov. 4 points it a reprieve is unlikely, for it could be based only exceptionally heavy rainfall together with a self- d economy of about 50%. Special arrangements een made for hospitals and bakeries, and the needs sick and old people will be met by 200 water- but householders will have to draw their water rry it from the nearest stand-pipe. Some 1200 to tands will be set up and there will be a 24-hour . The central city area is excluded because of of fire, and supplies to industry will be maintained, a 10% reduction in consumption is asked for.

appeals for economy have been disappointing. eal was made to the public on Oct. 21 for a 40% on, but at the end of a week the actual saving was and at the end of a fortnight 7½%. The restric- vill affect some 1,200,000 people in Manchester e surrounding towns.

Dysentery in Mental Hospital

utbreak of Flexner dysentery which started at kshire Mental Hospital, Wallingford, on Sept. 22, d 363 cases up to Oct. 31. There have been hs, all in old people who had recovered from te attack; and in them the infection is thought been only an associated cause of death.

een Sept. 22 and Oct. 20 there were 15 cases, Oct. 21 an explosive outbreak began; this ed up to Oct. 29, the daily total of new cases from 20 to 72. Since then there have been only cases a day. Until Oct. 17 all cases were from a ward; on that date prophylactic sulphaguanidine ent was instituted in this ward, from which there een no further cases.

first infection manifested itself by rigors, high and diarrhœa with typical dysentery stools, t gross constitutional disturbance. Later, how- here was vomiting in all cases; patients were ed, often with extreme dehydration, but the stools ot so typically dysenteric. The attack has never longer than forty-eight hours. The outbreak oved the advantage of taking rectal swabs for iological examination. Investigations are not mplete, but the source is believed to have been a t employed in the kitchen, who was a carrier.

Poliomyelitis and Polioencephalitis

ifications of poliomyelitis in the week ended Oct. 25 red 251 and were fewer than in the previous week but notifications of polioencephalitis rose from 12 The trend of polioencephalitis returns has not ery consistent, and probably there are considerable nces in the meaning attached to this term.

visional figures of registrations of deaths from yelitis and polioencephalitis supplied by the rar-General are as follows: July, 74; August, 206; nber, 160. It is, of course, impossible to relate very directly to notifications, because of the g duration of illness and possible delay in the ation of death, but the total of notifications relat- roughly the same periods suggests a fatality-rate order of 7%. Preliminary analysis of deaths by ggests that the increase in the fatality of the e in older age-groups which has been reported in countries has also been a feature of this epidemic. hoped that more information on this and other rs will be derived from the survey of hospital cases eing undertaken by the Ministry of Health.

nfectious Disease in England and Wales

WEEK ENDED OCT. 25

ifications.—Smallpox, 0; scarlet fever, 1452; ping-cough, 1003; diphtheria, 238; paratyphoid, yphoid, 4; measles (excluding rubella), 1981; pneumonia (primary or influenzal), 482; cerebrospinal fever, 34; poliomyelitis, 251; polioencephalitis, 29; encephalitis lethargica, 0; dysentery, 340; puerperal pyrexia, 125; ophthalmia neonatorum, 53. No case of cholera, plague, or typhus was notified during the week.

Of the 340 cases of dysentery, 260 were notified at Wallingford, Berks.

Deaths.—In 126 great towns there were no deaths from measles or scarlet fever, 1 (0) from enteric fever, 3 (1) from diphtheria, 1 (1) from whooping-cough, 69 (7) from diarrhœa and enteritis under two years, and 12 (2) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 254 (corresponding to a rate of 32 per thousand total births), including 32 in London.

Obituary

HAROLD BEN FAWCUS

K.C.B., C.M.G., D.S.O., M.B. DURH., D.C.L.

Sir Harold Fawcus's term of office as director-general of Army Medical Services covered the period 1929–34, and the reforms and adjustments of organisation made in 1926 and in 1935 were largely a reflection of his vision and influence. Indeed his retirement was postponed so that he might carry out the recommendations of the Warren-Fisher Committee, many of which he had sponsored.

Press Portrait Bureau

He was born in 1875, the son of John Fawcus of South Charlton, Northumberland, and was educated at Durham School and University, where he graduated M.B. in 1899. During the South African war he served at first as an attached civil surgeon till he received his commission in 1900. In 1905 he took his D.P.H., and the special certificate in State medicine which he obtained at his examination for major in 1911 led to his appointment as assistant professor in hygiene at the Royal Army Medical College at Millbank. Of the informal group which grew up there, with Leishman at its head, Prof. Lyle Cummins writes:

> We discussed things from the same point of view, and "discussed" the little dinners that we often had together with the same zest. Fawcus, Cumming, and I maintained a theoretical rivalry between what the old porter at the college used to call "Them 'Igenes" and the path. department as represented by Cumming and myself. Fawcus of course was quite capable of keeping his end up as the exponent of the department of hygiene.

In 1914 Fawcus was appointed an instructor at the Army School of Sanitation at Aldershot, but soon after the outbreak of war he became D.A.D.M.S., Lines of Communication. Later he served with the 3rd Army, under General Rawlinson, and as A.D.M.S., Guards Division. The war thus turned him into an administrator, but it was a principle of his that "in this war one can do anything if one only has a fortnight to pick up the details." As regards Fawcus, this was probably true. For his services he was mentioned six times in despatches, awarded the Croix de Guerre and the D.S.O., and appointed C.M.G.

After the war Fawcus became in turn assistant director-general and deputy director-general at the War Office, and in 1929 he succeeded Sir Matthew Fell as director-general of Army Medical Services, with the rank of lieut.-general. Of his work, a colleague writes: "Although Fawcus was shy, one of his outstanding characteristics was his imperturbability, and this added greatly to his strength as a good and wise administrator. His corps had a serene confidence in their director-general. He did not come to hurried conclusions, and where possible liked to consider all sides of a question. But when a recommendation was presented to him, which in his opinion was obviously right, he would pursue it with enthusiasm. He was invariably a long-view man, and measures for the prevention of disease met with his support as readily as the more spectacular side of his profession, for they appealed to him not only in the interests of the short-term serving soldier but also of the long-term reservist and of the general public health. Quick to realise the advantages of the use of efficient auxiliary personnel, Fawcus warmly supported the aims and object of the Army Dental Service established in 1921, holding it to be perhaps the most important step taken by the medical department in his generation."

General Fawcus left the department at his own request, a few months before his extended term of office had expired, to allow him to take up the director-generalship of the British Red Cross Society, on the death of Brig.-General Bateman-Champain. He retired from this post in 1938 and in the same year he was appointed colonel commandant of the R.A.M.C. He was also a commissioner of the Royal Hospital, Chelsea. In 1928 he was appointed C.B. and he was promoted K.C.B. in 1931. His own university conferred on him the honorary degree of D.C.L.

Sir Harold Fawcus leaves his widow, formerly Miss Mary Ross, with a son and three daughters. He died at Hillingdon, Middlesex, on Oct. 24.

JOHN WILLIAM GEARY GRANT

F.R.C.S.

Mr. J. W. Geary Grant died at the age of 81, on Oct. 23, at Weymouth, where he retired last year. He had been in active surgical practice for over 50 years and was consulting surgeon to the Royal Infirmary at Cardiff, where he lived for 34 years. The son of Admiral J. W. Grant, he qualified from St. Thomas's Hospital in 1890, and he took his F.R.C.S. in 1909. After holding house-appointments at Halifax Royal Infirmary and at the Evelina Hospital, he settled in Cardiff. For a time he was first assistant in the surgical unit of the Welsh National School of Medicine. In the 1914–18 war he was attached to the Western General Military Hospital, at Whitchurch, near Cardiff. His published work dealt mainly with abdominal surgery, and included articles on acute necrosis of the pancreas, carcinoma of the rectum, reversed rotation of the intestine, and traumatic and arteriovenous aneurysm. In 1944 in two articles in the *Medical Press* he recalled his experiences during Half a Century of Surgery.

Mr. Geary Grant is survived by his widow and by two daughters of his first marriage.

COURTENAY CHARLES WEEKS

M.R.C.S.

The Rev. Courtenay Weeks, honorary medical director and editor of the National Temperance League, died on Oct. 26 at Pershore. He was born at Portsmouth in 1872, the son of Rear-Admiral G. H. Weeks, and he took his *Conjoint qualification from University College* Hospital, London, in 1895. Even before he qualified he had become interested in the temperance movement, and he was president of the World Students' Federation against Alcoholism. After holding house-appointments *at the Coventry and Warwickshire Hospital* he practised for some years in South London before taking Holy Orders.

At the beginning of the war in 1914 he was vicar of St. Hilda, Crofton Park; but as there were no vacancies in the chaplain's department of the Services and a great need for surgeons he accepted a commission in the R.A.M.C., and he was in charge of the surgical work at the military hospital in Malta during the Gallipoli campaign. On his return to this country he served as surgeon at the Royal Herbert Hospital, Woolwich. In 1920 Dr. Weeks became a medical lecturer of the National Temperance League, and for this work both his professions provided valuable background. An effective and sincere speaker, he lectured at many public and secondary schools, and to the students of theological and training colleges as well as of the universities.

On behalf of the temperance movement Dr. presented evidence before the Royal C Licensing (1929) and the Select Committee of the of Lords on the prevention of road accidents in In 1932 he played an important part in organisi 20th International Congress on Alcoholism, and he wards made himself responsible for editing the of the proceedings. In 1925 he published his on *Alcohol in Medical Practice*, and in 1938 the edition of his *Alcohol in Human Life* appeared. a member of the council of the Society for the of Inebriety, though of late the war and ad years *had made it increasingly difficult for* attend their meetings, especially since 1940 became the rector of the Combertons in Worcest. But he continued his connexion with the Temperance League, holding honorary office death.

DR. RIDDOCH

R. A. H. writes: The death of Dr. George came as a most grievous blow to those who worke him. To his assistants he had always been th kindly of chiefs. He demanded a high standard o from registrars, housemen, and clerks, and he obtained it, even from the most unlikely materi took a real interest in his juniors and was always to help them in their later careers. His teaching legendary quality, and his demonstrations parti were marked by a beautifully logical exposit neurological problems delivered with an inimitable and enthusiasm. His memory for patients was *ordinary, and how they adored him.* He was tired end, but even so he would outlast the energy of his as he pursued a long ward round.

The photograph of Dr. Riddoch reproduced last w by Richard Day.

Births, Marriages, and Deaths

BIRTHS

ALBERTS.—*On Oct. 27, at Lichfield*, the wife of Flight-Li Frank Alberts, R.A.F.—a daughter.

BRADY.—On Oct. 10, in London, the wife of Dr. T. J. a daughter.

CROFT.—On Oct. 28, at Kenilworth, the wife of Dr. W. H. C a daughter.

CURL.—On Oct. 31, the wife of Dr. O. J. Curl—a son.

ESMONDE.—On Oct. 29, at Hong-Kong, the wife of Dr. P. E M.C.—a daughter.

HUGO.—On Oct. 24, at Guildford, the wife of Mr. Richar F.R.C.S.—a son.

RICE.—On Oct. 25, in London, the wife of Dr. David Rice—

SKEMPTON.—On Oct. 31, the wife of Dr. I. P. D. W. Ske a son.

THORNTON.—On Oct. 29, at Edinburgh, the wife of Dr. Thornton—a daughter.

WYNN-WILLIAMS.—On Oct. 29, in London, the wife of Mr Wynn-Williams, F.R.C.S.—a son.

MARRIAGES

DENT—TEMPLETON.—On Nov. 1, at *Aberdeen*, Ronald M.R.C.P., to Mary A. Templeton, M.B.

DOWNMAN—BARAKAN.—On Oct. 24, in London, *Charle* Downman, M.R.C.S., to Thaïs Hélène Barakan, B.SC.

MACKAY-SCOLLAY—WELLER.—On Oct. 25, at Watford, Mackay-Scollay, M.B., to Mary Weller.

RHODES—BRAMLEY.—On Oct. 25, at Ashford, Middlesex, Stuart Rhodes, A.R.I.B.A., to Katerina Bramley, M.B.

DEATHS

BRAMWELL.—On Oct. 30, at Richmond, Yorks, Dan Cum Byrom Bramwell, M.B. Edin., aged 30.

BURGHARD.—On Oct. 31, at Cambridge, Frédéric *Burghard, C.B., M.D.,* M.S. Lond., F.R.C.S., colonel, aged 83.

GOBLE.—On Nov. 1, at Hayling Island, Frederick Georg M.R.C.S., surgeon captain, R.N. retd.

KAUNTZE.—On Nov. 4, William Henry Kauntze, C.M.G., M.I M.B. Lond., F.R.C.P., late chief medical adviser to the Office.

LYTLE.—On Oct. 26, Robert James Lytle, M.D. Belf.

NEWTON.—On Oct. 29, at South Broomhill, Morpeth, Gray Newton, M.B. Edin., F.R.C.S.E.

PIERCE.—On Oct. 26, in London, Ward Irving Pierce, M.D. L.M.S.S.A.

SCHWIZER.—On Oct. 22, George Clemens Schwizer, M.D. M.R.C.S.

TRUMAN.—On Oct. 26, at Nottingham, Bernard Renshaw Truman, B.A., M.B. Camb.

WEBBER.—On Oct. 26, at Sandown, I.o.W., Alexander Webber, M.S. Lond., F.R.C.S.

WEEKS.—On Oct. 26, at Pershore, Courtenay Charles M.R.C.S., rector of the Combertons, Worcs.

WELCH.—On Oct. 26, at Haslar, Sir George Welch, K.C.M. M.R.C.S., surgeon rear-admiral, R.N. retd., aged 89.

Notes and News

U.N. CHILDREN'S RELIEF FUND

ST December the United Nations International Children's rgency Fund was set up to aid needy children and ctant and nursing mothers in all parts of the world. approximate survey showed that at least 60 million ten in Europe and the Far East urgently required supple- ary feeding and other help. The fund is still handi- ed by lack of money; but aid is already being provided etween 4 and 5 million children in twelve European tries (Albania, Austria, Bulgaria, Czechoslovakia, Finland, ce, Greece, Hungary, Italy, Poland, Rumania, and slavia), and in the Far East. After visiting Europe , Mr. Maurice Pate, executive director of the fund, sed his conviction "that this winter will be the hardest the people of Europe have known in eight years of war eace."

Jackson, N. S. Jain, Sarah J. Jenkins, T. S.-B. Kelly, P. J. M. Kent, D. A. Langley, Marion McArthur, John McClemont, P. H. N. Matthews, W. S. Milne, D. G. Mody, E. S. Perkins, J. S. Phillpotts, F. C. Rodger, Maeve Rusk, M. H. M. Ryan, Q. R. Schindler, D. T. Shortridge, F. N. Shuttleworth, D. G. Simpson, C. S. Smalley, J. L. S. Smith, C. H. H. B. Sparrow, Geoffrey Sutherland, W. M. Walker, Nina S. S. S. Warwick, S. E White, Eunice M. Wilson.

D.T.M. & H.—G. M. Abraham, G. T. Allen, J. F. Britto, J. H. Cater, K. H. Cheung, S. Childs, J. H. C. Clarke, Lesley M. B. Copland, M. A. C. Dowling, A. J. F. Eberle, E. N. Emmerson, Zarina A. Fazelbhoy, S. K. Ganguli, V. T. H. Gunaratne, M. T. Gyi, Vera W. D. Hall, K. P. Hare, W. D. Hughes, J. P. F. Hummel, M. P. Hutchinson, Frances C. Kerr, S. N. Kothare, Phaik-Lin Lim, N. W. Low, P. C. Mahanty, B. K. Naik, A. A. Odier, A.-H. A.-R. Omar, C. P. Patel, D. N. Patel, A. J. Patterson, R. A. O'G. Pearson, H. J. A. Richards, J. G. Salter, R. S. Saxton, J. C. Shee, R. P. Shields, W. P. Stamm, K. G. B. Stork, Robert Symons, W. F. J. M. Thom, Emanuel Tuckman, H. W. Wheate, Hanna H. Wozniak, G. B. Wright.

D.M.R.-D.—Ifan Ap Thomas, Eric Batley, J. L. Boldero, J. S. Campbell, P. S. G. Campbell, A. F. Crick, C. G. Edwards, J. B. Fawcitt, David Hector-Jones, A. K. Lamballe, M. W. H. Mackay, Elsie L. Mettam, W. R. Parker, J. N. Pattinson, E. N. Pearlman, S. P. Rawson, David Sutton, B. W. Thomas, J. M. W. Wells, C. G. Whiteside.

D.M.R.—K. W. Beetham, D. G. Bratherton, E. C. Easson, J. M. W. Gibson, Herbert Holden, K. S. Khambata, N. S. Lockyer, J. L. E. Millen, T. K. Morgan, B. A. Stoll.

D.P.H.—Alexander MacFarlane.

D.L.O.—Ben Cohen.

D.Phys.Med.—A. C. Boyle, M. C. Woodhouse, Andrew Zinovieff.

University of Glasgow

The following degrees were conferred on Nov. 1:

M.D.—Patrick Macarthur (with commendation); F. J. Hebbert, J. E. Tillotson.

Royal College of Surgeons of Edinburgh

At a meeting held on Oct. 29 the following office-bearers were elected for the ensuing year: president, Mr. Frank Jardine; vice-president, Mr. James Graham; secretary and treasurer, Mr. K. Paterson Brown; members of the president's council, Sir John Fraser, Dr. G. Ewart Martin, Mr. W. Quarry Wood, Mr. Walter Mercer, Prof. J. R. Learmonth, and Dr. W. F. Theodore Haultain; representative on the General Medical Council, Sir Henry Wade; conservator of museum, Mr. J. N. J. Hartley; convener of museum committee, Mr. Quarry Wood; librarian, Dr. Douglas Guthrie.

The following were admitted to the fellowship:

John Aitken, M.B. Glasg., H. M. Bennett, M.B. Belf., S. M. Bootor, M.B. Cairo., Y. G. Bodhe, M.B. Bombay, E. S. Brawn, M.R.C.S., J. E. S. Carmichael, M.B. Edin., Florence Cavanagh, M.B. Melb., D. H. Clark, M.B. Glasg., J. C. Comline, M.B. Edin., W. T. Cumming, M.B. Edin., J. B. Cuthbert, M.B. Lond., N. M. B. Dean, M.B. Edin., Derrick Dencer, M.R.C.S., M. D. Desai, M.B. Madras, G. de L. Fenwick, M.B. N.Z., W. J. Fraser, M.B. Edin., Debabrata Ghose, M.B. Calcutta, I. L. Gregory, M.B. Manc., A. P. Guttman, M.D. Manitoba, J. A. V. Hamilton, M.B. Glasg., H. El S. Higazi, M.B. Cairo, R. M. Hugo, B.M. Oxfd, John Huston, M.B. Belf., G. C. W. James, M.R.C.S., J. M. Jones, M.B. Lond., V. A. F. Martin, M.B. Belf., Esmond Millington, M.R.C.S., J. C. G. Moore, M.B. Dubl., George Murdoch, M.B. St. And., A. M. Murray, M.B. Glasg., M. P. McCormack, M.B. Edin., C. G. G. Mackay, M.B. Edin., F. D. Mackenzie, M.D. McGill, D. L. Poddar, M.B. Calcutta, E. W. Price, M.B. Camb., Agnes R. Russell, M.B. Glasg., W. H. Scrase, M.B. Birm., Emanuel Seidenman, L.R.C.P.E., N. C. Sen, M.B. Calcutta, N. C. Shah, M.B. Bombay, H. V. Shaibany, M.B. Lond., K. J. Sheth, M.B. Bombay, D. W. Short, M.B. Glasg., F. MacN. Smith, M.D. Alberta, C. E. E. Stevens, M.B. Belf., F. V. Stonham, M.B. Melb., J. W. M. Sutherland, M.B. Aberd., A. F. Torrie, M.B. Edin., S. L. Townsend, M.B. Melb., H. M. Urquhart, M.B. Edin., C. H. Vipond, M.D. Queen's Univ., Ontario. R. G. Maclagan Wedderburn, M.B. Edin., V. H. Wheble, B.M. Oxfd, J. S. Young, M.D. Queen's Univ., Ontario.

Franco-Anglo-American Medical Society

At a meeting of this society at 11, Chandos Street, London, W.1, at 2.30 P.M., on Tuesday, Nov. 11, with Lord Horder in the chair, the subject of discussion will be a joint research programme with the French in evolution of the society's international climatic health service, preparatory to reopening in 1951. All interested, lay or professional, are invited to take part in the deliberations. The acting hon. secretary of the British section is Dr. F. Aylmer Hort.

Contributions for Europe

In connexion with its appeal for the relief of distress on the Continent this winter, the Save Europe Now organisation (15, James Street, W.C.2) announces that during the week Nov. 30 to Dec. 7 temporary depots will be set up all over London for receiving gifts of rationed food, second-hand clothing and shoes, second-hand linen, and books. The organisers will be grateful for offers to provide such depots anywhere in the London area.

National Insurance Advisory Committee

The Minister of National Insurance has appointed a committee to assist and advise him in the operation of the National Insurance Act, 1946. The committee will shortly begin to consider the draft regulations for the Act which the Minister is required to submit to them, and all persons affected will have an opportunity of putting before them any objections to the regulations. Sir Will Spens has accepted the chairmanship of the committee and the eight members include Dr. John Ritchie, formerly M.O.H. for Dumfriesshire.

Conference on Mental Health

The National Association for Mental Health is to hold a conference at Seymour Hall, London, W.1, on Jan. 15 and 16. Subjects and speakers include: re-adaptation to life and work of persons who have suffered from nervous or mental disorder (Dr. G. R. Hargreaves, Dr. Donald Stewart); the handling of difficult children (Mr. E. M. Bartlett, PH.D., Miss Clare Britton); the responsibilities of local authorities in relation to mental health (Dr. Kenneth Soddy, Dr. Doris Odlum); and education for mental health as a national and international responsibility (Brigadier A. Torrie, M.B., Dr. J. R. Rees). Inquiries should be addressed to the conference secretary at 39, Queen Anne Street, London, W.1.

Pharmacy Working Party

A working party has been appointed by the Minis Health and the Secretary of State for Scotland to in the differences between the work of pharmacists in E and Wales and in Scotland in dispensing and medicines and appliances, with particular reference t position likely to arise under the National Health Serv

Middlesex County Council is to make [illegible] the Minister of Health with a view to obtaining an [illegible] allocation of meat, bacon, and fats for patients [illegible] institutional treatment for tuberculosis.

Appointments

Middlesex Hospital, London:

LAWRIE, R. S., M.D. Lond., M.R.C.P., F.R.C.S.: first professorial surgical unit.

LE QUESNE, L. P., M.A., B.M. Oxfd, F.R.C.S.: second professorial surgical unit.

PAULLEY, J. W., M.D. Lond., M.R.C.P.: first assistant, pr medical unit.

PILE, G. C. L., M.A., M.B. Camb., F.R.C.S.: senior department of thoracic surgery.

SEMPLE, ROBERT, M.B. Aberd., M.R.C.P.: second professorial medical unit.

Diary of the Week

NOV. 9 TO 15

Monday, 10th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
6.15 P.M. Mr. E. D. D. Davis: Malignant Disease of the P
SOCIETY OF APOTHECARIES OF LONDON, Black Friars Lane,
5 P.M. Prof. S. J. Cowell: Recent Trends in Diet Therapy
MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8.30 P.M. Dr. William Evans: Cardiac Pain.

Tuesday, 11th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Mr. Harold Nicolson: Health of Authors. Roberts lecture.)
ROYAL COLLEGE OF SURGEONS
6.15 P.M. Mr. John McGibbon: Otitis Media in
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
5 P.M. *Psychiatry.* Dr. Fraser Steele: Assessment of in Psychiatry.
INSTITUTE OF DERMATOLOGY, 15, Lisle Street, W.C.2
5 P.M. Dr. I. Muende: Pathological demonstration.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
5 P.M. (Royal Infirmary.) Prof. W. S. Tindal: Modern A to Miracles.

Wednesday, 12th

ROYAL SOCIETY OF MEDICINE
4.30 P.M. *Physical Medicine.* Dr. W. Russell Brain and D. W. C. Northfield: Brachial Neuralgia.
5 P.M. *Proctology.* Mr. A. Dickson Wright: Total Colect (Presidential address.)
SOCIETY OF APOTHECARIES
5 P.M. Dr. Frank Howitt: Rehabilitation.
ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Port Place, W.1
3.30 P.M. Prof. W. C. W. Nixon: Diet in Pregnancy.

Thursday, 13th

ROYAL COLLEGE OF SURGEONS
5 P.M. Sir Cecil Wakeley: Vogue and Fashion in Abdomi Surgery. (Bradshaw lecture.)
ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS, 58, Que Anne Street, W.1
5 P.M. Mr. D. J. MacRae: Heart Disease in Pregnancy. (Bl Bell lecture.)
ROYAL SOCIETY OF MEDICINE
5 P.M. *Ophthalmology.* Mr. D. D. Stenhouse-Stewart Dr. A. A. Newth: Policy in Dealing with Partially Sigh and Blind Persons.
SOCIETY OF APOTHECARIES
5 P.M. Sir Howard Florey, F.R.S.: Recent Advances in th Laboratory Investigation of Penicillin.
INSTITUTE OF DERMATOLOGY
5 P.M. Dr. J. L. Franklin: Cutaneous Neoplasms.
HONYMAN GILLESPIE LECTURE
4.30 P.M. (Edinburgh Royal Infirmary.) Dr. E. A. Carmichael Dynamics of the Cerebrospinal Fluid.

Friday 14th

ROYAL COLLEGE OF SURGEONS
6.15 P.M. Mr. W. A. Mill: Neurological Disorders of the Phar and Larynx.
TUBERCULOSIS ASSOCIATION
3 P.M. (Royal Empire Society, Craven Street, W.C.2.) D F. R. G. Heaf: Accommodation for the Tubercul (Presidential address.) Mr. Hamilton Bailey and D Suzette Gauvain: Tuberculous Glands of the Neck.
LONDON CHEST HOSPITAL, Victoria Park, E.2
5 P.M. Dr. J. R. B. Hern: Dyspnœa.
ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh
8 P.M. Mr. George Perkins: Broken Ankle.

THE HEALTH OF AUTHORS*

The Hon. HAROLD NICOLSON
C.M.G., F.R.S.L.

fully conscious that this evening I am addressing dience composed to no small extent of very able experts. However enthralling may appear to y views, either about health in general, or about m health, or about the health of others, I am that my interest in these subjects will be shared . My sense of audience, my sense of occasion, thus in any case deter me from advancing any l, or even psychological, theories. I shall not do Indeed I possess two qualifications only for the efore me. I have devoted much of my life to dy of the literary temperament: and I have e good fortune to know, and sometimes to know ely, many of the leading writers of my own y and of other countries. All I can hope to do is before you, as simply as I can, the results of this nce.

much for the problem of audience. What about oblem of subject? The title of this lecture contains, will have observed, two operative words—namely, h" and "authors." I shall not trouble you much the physical health of famous writers, except far as I shall seek to disprove the popular fallacy *ll mighty poets must be of an ailing constitution* oomed to an untimely death. I shall be concerned with the mental health of authors and more ally with that form of nervous activity, or lity, which enables its possessor to receive—if I beg the question for a moment—"intimation" inspiration." In other words I shall seek to examine he mind of the creative writer works.

what sense again, to complete these introductory tions, shall I be using the word "author"? We nd, when viewing from outside the members of any g or profession, to regard them as constituting a m category or type. *I am aware, for instance,* I myself am inclined to regard lawyers as a type, ldiers as a type, or sailors as a type. They also, quite sure, regard all writers, whether they be ive writers or hack writers, as more or less uniform, he almost indistinguishable components of a small tric clan. Yet *although the prolonged pursuit* y calling is undoubtedly apt to impose a certain rmity of mode, manner, speech, and even counten- , the members of such a calling—however strong be their herd instinct—do not regard each other niform; but as multiform. The *outsider* observes superficial similarities; the *insider* notices only the idual dissimilarities. In using the word "authors" it designated a category or class I am thus aware I am using a term which has but little meaning. include within that term all those who earn their g by the pen would be to extend the area of my ury to a quite unmanageable circumference. I shall efore restrict myself to those writers who can justly alled "creative," in the sense that by the force heir imagination, or the delicacy of their perception, have discovered new combinations of experience. since of all writers poets are, within this meaning he term, the most "creative," I shall in general entrate my observations upon the behaviour and perament of poets. Within these restricted limits all have certain information to give and certain very ative suggestions to advance.

THEIR BODILY HEALTH

referred just now to the popular fallacy that all tive writers, and especially all poets, are of weak bodily constitution and as such liable to premature death. This fallacy has arisen, not so much because a large proportion of poets have suffered untimely death, but because almost all poets have imagined, and have loudly proclaimed, that they were destined to die young. I should hesitate to deny—although I shall carefully refrain from examining—the oft-repeated theory that there exists some affinity between the literary and the consumptive disposition. There is little doubt that, in the 19th century at least, a high proportion of creative geniuses (and the names of Keats and the Brontës occur to one immediately) succumbed to tuberculosis. Yet if one examines objectively the mortality statistics of eminent writers one does not find that their bodily, as distinct from their mental, health (and I am aware that this is a dangerous distinction)—one does not find, I say, that their bodily health was any worse than that of their illiterate contemporaries. If, for instance, one takes a list of the thirty-two most famous British poets who flourished between the middle of the 14th century and the end of the 19th, one is struck by the fact that, given the contemporary expectation of life, they were remarkable for their longevity. Of these thirty-two famous poets as many as ten lived beyond the age of 70, nine died between the ages of 60 and 70, seven between the ages of 50 and 60, two between the ages of 40 and 50, and only four under the age of 40. Nor should we forget that many of these mighty poets did not, during their lifetime, take that care of their health which their medical advisers would have recommended. Ben Jonson and Michael Drayton, as we know, were of a convivial disposition, and in fact some authorities have attributed Shakespeare's final illness to the effects of their uproarious visit to Stratford a few weeks before his death. Yet Ben Jonson lived to the then ripe age of 65 and Michael Drayton to the age of 68. Herrick and Marvell were not particularly austere, yet each of them lived to over 70. Swift and Dr. Johnson during their lifetime were tortured with the dread of premature decay, yet Swift retained his bodily health at least until the age of 77, and Johnson was 75 at the time of his death. Tennyson again, who during his middle life was a confirmed hypochondriac, lived to the venerable age of 83; and Swinburne, whose early manhood was not distinguished by any pronounced asceticism, lingered on at Putney until his 74th year. I doubt whether if one examined the lives of thirty-two famous clergymen, lawyers, or merchants between the 13th and the 19th centuries one would find that they could show an equally high average of survival.

And what of the four mighty poets who did in fact suffer an untimely death? Keats, it is true, died of consumption in Rome at the age of 26; but the deaths of Marlowe and Shelley were due, not to health, but to accident. Marlowe was killed at the age of 29 in a tavern brawl at Deptford; and Shelley at the age of 30 was drowned in a squall off Viareggio.

There are those who contend that the fourth of these premature deaths, the death of Byron at the age of 36, was also due to an accident. Such people aver that, but for the incompetence of the local doctors at Missolonghi, Byron would have survived to a reputable and perhaps repentant old age. This assertion is to my mind an unfair reflection upon the professional skill of Doctors Bruno and Van Millingen. As I have devoted much study to the last illness of Byron, and as it still constitutes one of the unsolved medical mysteries of literary history, you will perhaps allow me, in fairness to his much abused doctors, to digress outrageously for a moment and to examine the facts of the Byron case.

According to the accepted story, Byron died of a rheumatic fever at Missolonghi, induced by rowing in an open boat across the lagoon after being heated by riding and drenched by a thunderstorm. His doctors are accused of having failed to

---

he Lloyd Roberts lecture for 1947, delivered before the Royal College of Physicians on Nov. 11.

diagnose his illness and of having bled him to death. The facts do not confirm this theory. People forget to mention that on Feb. 15, 1824, two months before his death, Byron was struck down by a convulsive fit, which he himself, perhaps incorrectly, assumed to be epileptic. On the advice of Major Parry, he treated himself for this affliction by drinking enormous quantities of cider laced with strong insertions of brandy: I cannot believe that in the paludal climate of Missolonghi that was a wise thing to do. It is quite true that in April he was drenched in a thunderstorm and that two days later he went out riding on a saddle which was still wet. Yet if his ten days' illness, which lasted from April 9 to April 19, was in fact rheumatic fever it is strange that he did not suffer the intense pain associated with that illness and even more strange that he was able on April 14 to walk unassisted from one room to the other. Nor is there any mention in the many accounts of his illness either of the heavy perspiration or of the swelling joints which rheumatic fever, as I understand, invariably produces. I am advised indeed by those experts whom I have consulted, that Byron's final illness must have been either typhoid or pernicious malaria.

And what about the famous accusation that Drs. Bruno and Van Millingen bled their patient to death? They may have wished to bleed him copiously, but they did *not* succeed. Obstinately he refused to be bled until almost the last moment, remarking, perhaps not inappropriately, to Dr. Bruno that "the lancet, as he well knew, had killed more people than the lance." It was only on April 16, three days before his death, that he at last consented to be bled. According to Dr. Van Millingen's account he stretched out his arm with the angry words "Come; you are, I see, a damned set of butchers; take away as much blood as you will; but have done with it." This is confirmed exactly in Dr. Bruno's account, who records him as "prestando il braccio in una maniera disgustosa." They then drew a full pound of blood but the fever did not, to their surprise, subside for long. It may well be that, in his then condition, a pound of blood was an excessive quantity to have drawn; but I am assured that in so doing Byron's doctors were in no way violating the conventions of their age. And I doubt whether, even if, as was hoped at one time, an English doctor could have reached him from the garrison at Zante or Corfu, this consultant would have made any very different diagnosis or have prescribed any very different treatment.

The death of Byron was undoubtedly a misfortune, but we should be unfair to Drs. Bruno and Van Millingen were we to perpetuate the legend that it was also an accident.

In any case I have, I suggest, said enough to indicate that the bodily health of authors, if I may venture such an expression, is as sound as that of the members of any other calling. I must now pass to the more interesting consideration of their mental health, or, as I should prefer to phrase it in less controversial terms, to a consideration of the literary temperament.

THEIR MENTAL HEALTH

The theory that there exists some special connexion between literary genius and mental derangement is one which, to my mind, has been seriously exaggerated. It is true that a few creative writers have in their later years become demonstrably insane; it is also true that almost all creative writers have at some moments of their lives been panic-striken by the conviction that their imagination was getting the better of their reason; but it is not in the least true that *all* creative writers have been mad *all* the time.

I must admit that the authorities for this distressing theory are both honourable and ancient. Plato contended that there were two forms of what he called delirium—namely, insanity and inspiration. "I have observed this about poets," he writes in the Apology. "It is not by taking thought that they create what they create; it is owing to a natural disposition and when ecstatically possessed." Burton, in *The Anatomy of Melancholy*, gives us the short sharp phrase "All poets are mad." Shakespeare assures us that—

> "The lunatic, the lover and the poet
> Are of imagination all compact,"

he speaks of "the poet's eye in a fine frenzy and in the less familiar conclusion to this famous he gives us the following suggestive lines:

> "Such tricks hath strong imagination,
> That, if it would but apprehend some joy,
> It comprehends some bringer of that joy,
> Or in the night, imagining some fear,
> How easy is a bush supposed a bear!",

Dryden in *Absalom and Achitophel* gave popular to this idea in his perhaps too well-known con

> "Great wits are sure to madness near allied;
> And thin partitions do their bounds divide

Macaulay goes so far as to say "perhaps no can be a poet, or can even enjoy poetry, without a unsoundness of mind." And Lamartine speaks mental malady which men call genius."

I could, if I so desired, extend by any nu quotations the comments which writers have upon their own mental derangement. I have enough however to establish the point that wri themselves largely to blame if the general public them as unbalanced. In their lack of reticence, self-conscious habit of examining their nerves in it is they, rather than the outsiders, who have the legend of their instability.

Yet the legend persists. As an example of the to which it can be pushed I should refer to M Nisbet's well-known book entitled *The Ins Genius*, which was published in 1891, and whic year since then has caused a great amount of a large number of people. "Genius and in writes Mr. Nisbet, "are in reality different pl morbid susceptibility of, or want of balance *cerebro-spinal system.*" *In the* strictly medic this may, for all I know, be true; but it is distre a creative writer, and disturbing for his fam descendants, to be told that what he and they to be a glorious boon from Apollo is in fact r than a diseased condition of what I understand the *medulla oblongata*. Mr. Nisbet, moreover, a from time to time he will let fall a word or two of examined the case-histories and the family hist distinguished writers with sadistic glee. If the father or grandmother of an author can be st have possessed a weak chest or a tendency to rheu their unhappy grandchild is accused by Mr. N being congenitally neurotic. I am not exagg Let me quote the relevant passage from Mr. cruel work. "Genius," he writes, "insanity, scrofula, rickets, gout, consumption and other n of the neuropathetic family of disorders, are s different expressions of a common evil—an ins or want of equilibrium, in the nervous system.' not saying that, in a technical sense, this may be true; but surely if one applied similar all-en tests to the case-histories and the family hist civil servants, bankers, postmen, and even a one would arrive at a closely similar result. To that a man is liable to mental derangement because his uncle suffered from gout is to a contention which, you *will agree, is palpably* Of course all creative writers are nervous; even that complacent hedonist, referred to them *genus irritabile vatum*—"that tetchy breed of b but to be nervous, even to be extremely nervo not necessarily imply that one is suffering from a disease.

It is for these reasons that I reject the extreme i tion which is suggested by Dryden's couplet and has been expanded in Mr. Nisbet's long, and admit extremely interesting, book. But it is not merely to reject the imputation. I must exam evidence and make at least some suggestions as in the minds of creative writers themselves, the d has arisen.

THEIR LATER YEARS

few eminent writers have, it must be admitted, sed in their later years into a state of idiocy. Others honestly be described as "borderline cases." And st all creative writers have been convinced at one or another that they were about to lose the control eir own brain.

t of the thirty-two famous British poets whose vity I commended at the outset of this lecture, two became demonstrably insane. Swift throughout fe was haunted by the spectre of insanity. "I shall ke that tree," he once said to a friend, indicating caying elm, "I shall die from the top." Yet Swift ct lived to the age of 77 and it was only in st three years of his life that his intellect became led. William Cowper, the "stricken deer" of Lord d Cecil's beautiful biography, was subjected from 21st year to recurrent fits of melancholia and dal mania. Twice in his life he almost succeeded nging himself and was only saved by chance. Yet ugh Cowper had twice to be placed in confinement, least under supervision, he enjoyed long interludes erfect sanity, during which he composed much llent poetry and was happy in a quiet tea-party of way. It cannot be said that Cowper was ever mented maniac; the worst that could be said of him that he was sometimes sadly confused in the head.

r. Johnson might, I suppose, be regarded (and would inly be so regarded by Mr. Nisbet) as a borderline . He suffered at times from auditory hallucinations he cherished many strange delusions, such as his f that he would get drunk if he ate an apple. He , poor man, obsessed by the dread of losing his . "Insanity," records Boswell, "was the object is most dismal apprehension, and he fancied himself ed by it, or approaching to it, at the very time when was giving proofs of more than ordinary soundness vigour of judgement." There is no evidence that this d was anything more than one of Dr. Johnson's y harmless delusions. But he certainly pushed it He entrusted his secret to Mrs. Thrale, and whenr he felt that madness was approaching, he would suade her to lock him in his room and it seems to e gyves upon his legs, and even to whip him with d. Certain obscure references in Mrs. Thrale's journal letters, and in the Doctor's own diary, can only be rpreted in this sense. But although Johnson was appily convinced of his own impending mental apse, he in fact retained his sanity to the very end. died of asthma and dropsy at the age of 75.

o these borderline cases Mr. Nisbet would I suppose that of Southey. It is true that in his 70th year they's mind became clouded twelve months before death. It is true also that Carlyle, after a visit from they, exclaimed "how has this man contrived, h such a nervous system, to keep alive for near 60 rs?" But there is no real evidence to suggest that they, except during the last twelve months, was thing but certifiably sane.

ECCENTRICITY: THE CASE OF SHELLEY

f therefore, out of my thirty-two famous British ts, only two can be described as definitely mad, and y one can with justice be classified as a borderline e, how comes it that the legend of mental illness among ative writers has been so persistent? That, I repeat, to a very large extent the fault of the writers themves. All writers, and especially all poets, feel it dull be thought completely normal. They thus divulge d even display their eccentricities. Nor should I ny that these eccentricities exist. Let me give you the ample of Shelley.

I should describe Shelley as on the whole a sane and normal person. One has only to read his *Defence of Poetry*, or his *Julian and Maddalo*, to realise how stable, except in moments of excitement, was the poise of his mind. Yet from his childhood Shelley had possessed what his mother would have described as "a highly strung nature," and the passionate rages into which he was thrown by being bullied at Eton caused him to be known by his school-fellows as "mad Shelley." The facility with which English schoolboys attribute insanity to anyone who is not perfectly attuned to their own herd behaviour has always struck me as curious and distressing. Shelley was certainly not mad; but he was eccentric, and his eccentricity took two particular forms.

In the first place he was a hypochondriac. All creative writers are hypochondriacs, since those of them who do not worry about the state of their bodies are certain to worry about the state of their minds. Shelley, having little gift of self-criticism, seldom regarded himself as mentally afflicted, but he persistently regarded himself as very very ill. Hogg speaks of his "unfounded frights and dislikes, his vain apprehensions and terrors." It was no comfort to him that his doctors, and even his moneylenders, insisted that his was a thoroughly good life in the insurance sense of that term. He was convinced that he was consumptive and entering upon a decline. Even when consumption ceased to obsess him he would invent fresh diseases with which to lacerate his anxieties.

> On one occasion he found himself in a crowded stage-coach opposite a lady whose legs were unusually distended. He had recently been reading a book of travels in which there was a description of the disease known as elephantiasis or Barbados leg. He jumped to the conclusion that this disease must be contagious and that he had caught it from the lady with thick legs in the coach. Within a few hours he observed upon his hands the symptoms of cracked and roughened skin which, as he had read, were the presages of this dire disease. Two days later, while sitting in an armchair talking to Mr. and Mrs. Newton, he fell writhing upon the carpet. His hostess, in pardonable anxiety, asked him what was wrong. He informed her, still writhing, that he had been assailed with a sudden and acute attack of elephantiasis. And, according to the testimony of both Hogg and Peacock, he persisted in this unhappy delusion for several weeks.

The second form assumed by Shelley's eccentricity was that of spectral and auditory hallucinations. It is customary for very gifted writers to see spectres and to hear voices calling. After all, even Goethe (who assuredly was a man of the most Olympian calm and sanity) once met himself riding along a road on horseback. Shelley's hallucinations were vivid and detailed. On one occasion, while walking near Pisa, he saw a man coming slowly towards him dressed in a long cloak and with a hood or cowl hiding his face. When the man was only a few yards distant he raised his hood, and Shelley was much startled to see that the man was in fact himself. The spectre then addressed a question to him in the Italian language. "*Siete sodisfatto?*" it asked him, "Are you satisfied?" At which the spectre vanished or passed on. On another occasion, at Lerici, Shelley saw a baby rise from the sea and clap its hands at him. These are, in so far as I know, the only two recorded instances of Shelley's hallucinations; but it is evident from the writings of his friends that these sounds and visions were of not infrequent occurrence. And yet Shelley, I repeat, was certainly not mad.

If one is to account for these departures from reality, one can only do so by considering in what manner creative writers, and especially poets, are inspired. Inspiration is a sudden flash or fusion between sense and fantasy, between reason and imagination. It is generally both a confusing and an exhausting episode, and one which often leaves behind it a bruise in the mind. "Such tricks," wrote the greatest of all poets in the passages I quoted earlier—"Such tricks hath strong imagination."

I now propose, in my concluding sections, to make some reflections upon the nature of inspiration such as will, I trust, convince you that the illusions—or if you like, the hallucinations—of creative writers are not grave symptoms of mental alienation but merely the tricks which a strong imagination is all too apt to play.

DIVERSITY OF TEMPERAMENT

I stated at the outset of this lecture that it would be an error to regard all authors, or even all creative writers, as constituting a uniform category or type. They are in fact multiform. Even in their methods, their hours, and their habits of work they display an astonishing diversity.

There are those, for instance, who possess the intense powers of concentration so startlingly manifested by Archimedes and who would agree with Newton, and also with Thomas Edison, that all creative thought is due to "patient attention." Such writers, and Wordsworth was one of them, can only bring their work to completion by agonised plodding along a single road. Others prefer a constant variation of theme. Thus Jane Austen kept *Sense and Sensibility*, *Pride and Prejudice*, and *Mansfield Park* upon her desk in various stages of completion, and would flit from one to the other. Burns and Beethoven were often engaged upon two or three themes at the same moment. And de Musset expressed the view that it was good for the mind to have a "twofold exercise."

Some geniuses can only begin to write in the silent privacy of their own studies, and to them even a blackbird calling becomes a person from Porlock. Others are actually stimulated by interruptions. Thackeray found that his ideas flowed more freely in the congested, if somnolent, atmosphere of the Athenæum Club. Mozart actually preferred when composing to be surrounded by the hum of general conversation, in which, incredible as it may seem, he would often participate. A similar talent, so I am told, was possessed by Sidney Keyes, that gifted poet who was killed in Tunisia at the age of 21. Keyes, it seems, was able to write poetry when surrounded by his undergraduate friends, and he would alternate his attention between composition of a poem and awareness of the conversation which was proceeding around him. And Schubert wrote one of his loveliest songs on the back of the bill-of-fare while sitting listening to the band in a public beer-garden.

Some authors find it more stimulating to commune with their muse in the early morning; others—such as Balzac, Byron, Dostoievsky, and Conrad—could only work well at night. Some people—and I am told that Miss Edith Sitwell is one of them—write best in a recumbent position; Voltaire at Ferney did most of his dictating from his bed. For others, movement is necessary. Many writers—and Dr. Johnson among them—have recorded that their ideas flowed more freely to the movement of a carriage or a train; Victor Hugo composed some of his loveliest lyrics when sitting on the top of an omnibus between Passy and the Bourse. Helmoltz has recorded that his mind never worked so rapidly as "during the slow ascent of wooded hills on a sunny day." Milton asserted that he could only write really well between October and March; other writers, including Tennyson, are more often inspired during the spring and summer. Even the technical tricks and habits of authors vary enormously. Schiller found it necessary to stimulate his unconscious by keeping rotten apples in the drawer of his writing-table. Thackeray, Mme. de Stael, and Southey found that their brains would only begin to ferment if they held an actual quill or pen in their hands; and many authors of my acquaintance have confessed to me that their ideas only begin to flow easily if the objects on their writing-table are arranged in a certain pattern. There are moreover few writers who would not agree that when stuck in a passage they find it necessary to leave their table
rapidly around the room.

I have quoted these divergencies of method
in order to indicate that if there in fact

upon the bark of a tree when walking; and T

es used to keep writing materials attached to alking-stick in order to take notes “ immediately ight darted.”

nost universal also is the sense of loneliness, lonment, failure, and pathetic incompetence which creative writers when the fleeting intimation has l by. Some of them complain bitterly that their has left them for ever and that they will never be o write again. Some of them resort to stimulants, s, or narcotics. Others do not believe in waiting ntly for the mood to recur but assert that the only od of recapturing inspiration is to go on slogging odically and hard. “ Work patiently every day,” Flaubert, “ and an equal number of hours.” ame dogged method was applied by Balzac, Trollope, o a certain extent Wordsworth also. Others seek ive their flagging imagination by listening to music reading the works of others. Milton, for instance, inspiration flagged used to spend his evenings ng his favourite poets in order, as he expressed it, tore his fancy against the morning.”

ers again, and they are the fortunate ones, rely t entirely upon what Mr. Graham Wallas has “ unconscious cerebration.” There can be little that this unconscious cerebration often works. said, for instance, that Swinburne suddenly thought e line “ Only the song of a secret bird ” and sat up hat night trying to hammer out a poem around it. led to come. When he woke up next morning he the whole poem out at a single sitting. The *Ballad of nland* which resulted is not, I admit, a very good tisement for the process of unconscious cerebration. ne remind you of the opening lines :

“ I hid my heart in a nest of roses,
Out of the sun's way, hidden apart ;
In a softer bed than the soft white snow's is,
Under the roses I hid my heart . . .”

so on. You will agree that unconscious cerebration t have done better. It is curious moreover that ugh poets have often woken up believing that they during their dreams composed a masterpiece, the s thus suggested prove, if written down, to be plete nonsense. Cerebration therefore ought not e quite so unconscious as all that. Mrs. Gaskell r admirable biography tells us that Charlotte Brontë ld often moon about for weeks and even months out being able to put pen to paper. And then lenly one morning “ the progress of her tale lay clear bright before her.” Perhaps the most deliberate cheerful practitioner of the method of unconscious bration was Sir Walter Scott. He always claimed the half-hour between waking and rising was for the most propitious moment for composition. “ This much the case,” he wrote, “ that I am in the habit elying upon it, and saying to myself when at a loss, ver mind ! We shall have it at seven o'clock tomorrow ning.’ ” Mr. Graham Wallas agrees with Sir Walter ott in advocating unconscious cerebration as a liberate method of, or device for, literary composition. In the case,” he writes, “ of the more difficult forms of eative thought . . . it is desirable, not only that there ould be an interval free from conscious thought on problem, but also that the interval be so ning should interfere with the free working cious, or partially conscious, processes of le mind.” It was with this idea, doubtless, that the ite Lord Balfour used to recommend to those of his taff who were suffering from overwork a three days' ourse consisting of detective novels and champagne. le would contend that by this method the blood was rawn away from the congested centres of the brain. And having on one occasion in my life been obliged o submit to, or to enjoy, this system, I am prepared to elieve that both Mr. Graham Wallas and Lord Balfour were correct. Nor would any regular writer or thinker deny for a moment that the effects of subconscious cerebration are frequent, beneficial, and mysterious.

THEIR RELATIONS WITH REALITY

I must now come to some conclusion. I have suggested that, in so far as concerns what as a layman I may perhaps be allowed to call “ bodily health,” the author is neither more, nor less, healthy than any other sedentary individual. The creative writer, the poet, and the artist do however possess a certain special nervous sensibility, which manifests itself not merely in their receptivity to inspiration but also in certain, apparently morbid, eccentricities. When poets and writers contend, as they so invariably do contend, that “ inspiration ” reaches them from outside they are describing an experience which is in no way abnormal but perfectly natural. It is true that these sudden and transitory intimations reach them from outside the area of their consciousness ; they reach them from their subconscious ; there is no need at all to drag in the supernatural phenomena of muses and daimons. Genius, in spite of Buffon and Carlyle, is not either a “ great aptitude for patience ” or “ a transcendent capacity for taking trouble.” It is a *spontaneous* activity of the cells and fibres of the brain whereby new combinations of impressions are constantly being formed. In insanity, as Mr. Nisbet has remarked, the nerve-connexions which should enable an individual to remain in touch with his surroundings are weakened or destroyed ; in genius these connexions remain intact. Yet there does often occur, in moments of inspiration or intense creative activity, some flooding of the conscious by the subconscious, and therefore some dissociation from reality. This mingling or flooding may in some cases produce extreme absence of mind and even hallucinations. More usually it creates that “ trance-like state ” to which W. B. Yeats referred. And almost always it produces some confusion between the imagined and the real, between the earthly life of the individual and the ideal world which he has peopled and conceived. “ Now let us talk of realities,” said Balzac to Jules Sandeau, “ let us talk about Eugenie Grandet.” It was this that Dickens meant when he said to Forster, “ I don't invent it : I see it and write it down ” or when he assured Lewes that he actually heard every word that his characters addressed to him. It was in this sense also that Flaubert, having described the suicide of Madame Bovary, felt a strong taste of arsenic in his mouth and was physically sick. No writer has ever composed or imagined anything of value without passing through these strange processes of identification. Yet such manifestations, I repeat, are not necessarily symptoms of morbidity ; in almost every case they are as natural to an author as are the leaves to the tree.

Be sure of one thing always. All authors are not of the same value or endowed either with comparable talents or with an identic temperament. At the bottom of the scale you have those men and women who, being gifted with a certain capacity for observation and narration, can both notice and annotate the world which swims around them. Such writers are as happy and unperturbed as water-beetles jerking with long prehensile legs along the surface of the village pond. In a higher scale come the novelists who from their memories and associations construct an imaginary world of their own which to them becomes one-half, and perhaps more than one-half, of reality. For them imagination is a diffused and comparatively constant frame of mind, and when inspiration comes to them, it comes, not as some intense and terrible visitation, but as a sudden and most welcome dissolution of an accumulated perplexity.

Raised above all others, living in a rarefied ether of their own, confused by the eternal dissonance between the ideal and the real, the mighty poets are a race apart.

For them imagination is no happy mood but a superb and agonised bewilderment. Not for them are the tiny pleasures, the small disappointments, the trivial success and failure, of the lesser breeds. The God visits them, not amicably, but in a flash of flame and fire; and in the after vacancy they know that they have caught but a momentary glimpse of intimation: their triumph is clouded by the knowledge that their illumination has been so narrow and so short.

Yet remember this also. No writer, however feeble he may be, can be of any value unless he possesses a powerful imagination; and powerful imaginations, as Shakespeare assures us—and he ought to know—are apt to play one tricks. Be kind, therefore, I beg you, to all authors, and above all to poets. Do not snub them when they assure you that they have caught elephantiasis from a lady in a bus; do not assume too solemn an expression when they confide to you that in Jermyn Street yesterday afternoon they met a gentleman in a tussore suit who, upon inspection, proved to be themselves; be gentle with them when they complain, as all authors have at every stage of their careers complained, that their mind and memory have crumbled and that the Muse will never visit them again. And never urge them in any circumstances to take a rest; no creative writer ever *can* take a rest; urge them only to embark upon some different sort of work, even if it be only detective novels and champagne. And remember always, I beg you, that they are seldom quite so mad as they believe; or as they seem.

PREFRONTAL LEUCOTOMY AND THE DEPERSONALISATION SYNDROME

H. J. SHORVON
M.B. Lond., D.P.M., D.A.
PSYCHIATRIC SPECIALIST E.M.S., SUTTON EMERGENCY HOSPITAL

THE distressing symptom of unreality both in self (depersonalisation) and surroundings (derealisation) can arise in the early stages of all neuroses and psychoses and in some organic conditions.

This paper is concerned with patients in whom depersonalisation is fundamental, the predominant and presenting symptom, existing almost alone as a clinical entity. Such cases of "primary" depersonalisation, or the "depersonalisation syndrome" (Shorvon et al. 1946) as it is often termed, tend to be of long duration and unvarying symptoms, and they are notoriously difficult to treat successfully. Psycho-analysis, convulsive and insulin shock therapy, abreaction techniques, and cerebral stimulants so far can claim few successes. Since these patients have insight into their condition they are often greatly distressed and may become seriously depressed or suicidal. They are intensely preoccupied with self, and there is a heightened self-awareness.

It is well known that a frequent after-result of leucotomy is a diminution in preoccupation with self and in self-awareness. Hence there are some a-priori grounds for using this operation in intractable cases of the depersonalisation syndrome where other methods of treatment have failed. In the Board of Control (1947) report on prefrontal leucotomy performed in 1000 cases there is only one mention of depersonalisation. The statement that "depersonalisation persists but less vivid" is included in a random group of follow-up returns, and there is no specific reference to the depersonalisation syndrome although it is frequently met with clinically. Freeman and Watts (1942) tabulate fifty symptoms showing various degrees of relief after leucotomy, and one of the listed symptoms is depersonalisation. Of 22 cases in which this symptom occurred, 19 showed a persistent relief of tion, 2 temporary relief, and 1 was unchanged. results are concerned with depersonalisation secondary symptom, and Reitman (1946) found results where the symptom occurred among symptoms in schizophrenics who responded orbital leucotomy.

Since practically nothing else has been sai depersonalisation in the extensive literature on experience of the operation in cases of intractable primary depersonalisation is record. The first 5 cases of depersonalisation in a series at the Sutton Emergency Hospital fo prefrontal leucotomy was performed are here. The later cases appear to be showing results.

FIVE CASE-RECORDS

Case 1.—A woman, aged 38, when first admitted t Emergency Hospital in November, 1944, under of Dr. Dalton Sands, complained of a sudden unreality three weeks after the birth of her third May, 1938.

Her father is morose, has bouts of silence, an punished her; her mother is highly strung, jealou stitious, and modest to the point of stupidity.

Patient was brought up very strictly, did well at and worked as a nursemaid and domestic until her in 1932. She had a child by a soldier before marri her husband was aware of this and did not consi problem.

Her personality before the illness was described as happy, energetic, and meticulous, with obsessional tions, phobias, and unshakable ideas.

She felt ill and weak after the onset of unreali recurrent attacks of panic, became depressed and at times, lost interest in her baby, and could not housework.

There was little change in four years; so she e mental hospital as a voluntary patient in 1942 and r eighteen months. Five 'Cardiazol' shock treatme duced no change. After five weeks at home she was rea and received ten electric convulsion shocks and a c continuous narcosis without benefit.

Early in 1944 she entered another mental hospita she was treated with thyroid without response, then attended for another six months a voluntary outpatient department, again without improvement.

On admission she said the illness began suddenly everything seemed to change and she felt a different "The outside world had gone wrong; the noise of th of the trees scraping the windows upset me; it was She blamed the anæsthetic used at the confinement an "I feel all the time I am talking about someone e myself; it seems as if all I do or say does not com the mind at all; all my thoughts appear to be func outside the room I am in; my head feels as if somet missing in it; I act the part and work quite automa I feel like a machine; it seems to be me; my head feel all my feelings have gone for my husband and ch time means nothing; the sun does not look brig nothing gives me pleasure; I don't enjoy food and on eating but never feel satisfied; my stomach feels like a shell."

She was dull and depressed and spoke in a mono tone but had insight into the abnormality of her th and this disturbed her emotionally. She had l sexual desire for six years, and was 3 st. under Depersonalisation syndrome in an obsessional pers was diagnosed.

Her husband considered that her condition was h since all treatments had failed, and readily agreed operation, adding: "You might as well otherwise shilling in the gas-meter."

Psychotherapy and a course of deep insulin had effect, and she showed recurrent episodes of tension, she became tearful and emotional and slept badly.

Mr. Wylie McKissock performed a prefrontal leuc in March, 1945, and there was considerable hæmo since she was restless and excited. In the evening sl restless, noisy, and mildly aggressive, and vomited persistently for some days. She was placid and ge

etic a week after the operation and the feelings of
lity were still present.

e weeks later she showed a complete absence of tension,
red fat and disinterested, and expressed little or no
on. Her condition then became fluid, and at times she
er old self and ceased to complain of depersonalisation
toms.

o months after leaving hospital she felt "pretty fit"
in her home but complained of little feeling towards
usband and family and tended to be sarcastic and
tempered.

ee months later she described herself as much better
ot quite right, since she was depressed at times, felt
rent, lacked affection, and did not derive the pleasure
hings that she would have got years ago.

ear after the operation she had no unreality feelings,
she said gradually disappeared after the operation, and
as definitely better except for some off days. Her
ons had improved, but she claimed to be more short-
red and irritable than before the illness: "I should
% cure; nothing worries me; I am interested in
hing and active."

r, 2½ years after the operation, she is cheerful, some-
disinterested, "lives for the day," and complains about
g on the level" all the time. . . . "I don't go up or
" She carries on normally at home, is even-tempered,
ets on well with her husband and children, but has
libido. There is some lack of affect, and she makes no
for the future. When asked if her husband thought
peration worth while she answers, "Oh, yes, definitely."
same question put to her brought the reply, "Of
e! I would rather live as I am now than then.
as terrible." She claims the operation has taken
all her dreadful fears and she has no symptoms of
onalisation.

husband reports: "She is now (Aug. 8, 1947) able to
with her normal duties, shopping, housework, &c., and
ition has taken on part-time work as a ward orderly at
pital. Her pace is much slower, but this may be due
having put on more weight. When it gets round to
. she has had enough and is ready for bed, and should
ave to stay up much after that she gets irritable. She
o interest whatever in the sexual act. Past events in
fe are hazy, and during conversation, whereas she would
ally think twice before giving an answer, she now says
comes into her head, whether it offends or pleases.
ugh she does get occasional spells of depression she is
to cope with them, and our life together is as happy
esent conditions will allow. The operation was far more
essful than I ever expected it would be."

is case demonstrates the gradual recovery after
otomy of a patient suffering from the depersonalisa-
syndrome for six years. The usual methods of
tment had failed. The operation was performed
years ago, and she is comparatively well, carrying
a fairly normal existence without any signs of a
pse.

ase 2.—A woman, aged 42, was readmitted to Sutton
March, 1946, complaining of persistent unreality and
ility to visualise for two years. This was her sixth and
t severe attack.

he had had a hard and difficult childhood owing to the
y death of her father, and had been brought up by
body who would look after her. The situation had
roved when her mother remarried, but her stepfather
harsh.

t the age of 2 years she lost an eye in an accident, and the
s eye induced a feeling of inferiority; but she did very
l at school, though unable to take up a scholarship for
ncial reasons.

he married at 19; her husband is quick-tempered, and
y often quarrelled. There were seven pregnancies, and
was ill with anxiety and vomiting in each. Her previous
sonality was described as anxious and obsessional, yet
ly, energetic, and a good mixer.

he first attack of depersonalisation occurred at the age of
after an upset, when her fiancé joined the Army and left
. She was distressed, and suddenly "everything went
nge, unreal, and I was a different person." She became
y frightened and had fears of insanity but made a
ntaneous recovery in a few weeks.

The second attack, at the age of 20, began three weeks after a severe first confinement and lasted three months.

A third attack ensued fourteen months later, three weeks after her second confinement, and lasted longer. It gradually passed off after a course of psychotherapy.

She was well after a third pregnancy two years later, but another spell of depersonalisation came on six weeks before the fourth confinement, and persisted well into the puerperium. During this pregnancy there was a good deal of domestic trouble, and her mother's death left her without help.

The next confinement two years later was uneventful, but a fifth attack of depersonalisation followed three weeks after the sixth confinement. She thought then she would never recover and would be better dead, but the symptom cleared after six months. She was free from symptoms at her final pregnancy and remained well for eleven years.

The present illness began in April, 1944, a month after an operation for hernia (apart from the anæsthetic with this operation, she had one during her first confinement). She described the onset and symptoms as follows: "I just sink into a kind of unconsciousness; I am just conscious enough to know that things are going on round me, but nothing seems to register; it is too far away to keep these things in my mind; I carry on automatically but I can't think; my body tries to work for the part of my brain that does not; I concentrate and get things a little back, but the strain is too strong, and as soon as I relax everything has gone again; my head is dead, and the part that makes life real has gone completely; I see things with my eyes but not with my mind; time is gone, is a blank; it is as if time has not been; every day goes into emptiness, it disappears, and I am not aware of its going; there is a gap between myself and realisation; everything is in a daze, far away."

This condition persisted with little variation in intensity. She was severely depressed and tearful and slept badly, and a course of ten electric convulsion shocks in outpatients produced no benefit. She was admitted to Sutton in April, 1945, when a further four electric convulsion shocks, psychotherapy, and insulin therapy were given without effect.

On readmission in 1946 she had lost 2 st. in weight and her condition was unchanged. Though she regained the weight-loss with the help of modified insulin, numerous therapies such as 'Benzedrine,' 'Epanutin,' cardiazol shocks, abreaction techniques, vasodilators, gland extracts, and psychotherapy were tried and proved futile. She remained a picture of hopelessness and despair.

Mr. McKissock carried out a prefrontal leucotomy in July, 1946. There were some mild behaviour disorders for a time after the operation, and for several days the patient answered only in a whisper, repeating that she was bodily tired and could not worry. Later she showed a curious mixture of apathy and mild elation, but a fortnight after the operation she said that she was quite well and had lost her feelings of unreality.

A week later she was euphoric, could visualise, had lost her disturbances in time, and was rather overactive and intolerant. She returned home cheerful and free from her symptoms of depersonalisation, though mildly euphoric and argumentative, and carried out very successfully her numerous and onerous domestic duties.

At a later interview she said: "I keep wondering how it is that I got well so suddenly; I can concentrate and visualise; I don't worry about tomorrow; I go to pictures and enjoy walks; I lose my temper a little and must argue, but I have to answer if I am right; I am not dead any more; sexual feelings normal." She has for some time now been doing her housekeeping, cooking for her husband and seven children, and managing a part-time job to supplement the family income.

Her husband reports (Aug. 10, 1947): "I think she is completely cured, because she does not worry any more and she does all the work in the house and goes for all the things that have to be got for a large family like ours."

In contrast to case 1, this patient made a dramatic recovery from her extremely severe depersonalisation symptoms very soon after leucotomy. She is now, a year after the operation, leading an active and useful life.

Case 3.—A man, aged 30, was first seen as an outpatient in May, 1942, when he said he had been invalided out of the

Army with an anxiety state and he wished to see a psychiatrist. He described the sudden onset of symptoms of unreality one morning in October, 1934.

Patient lived with his parents and two sisters. He was, and still is, frightened of his father, who is unsympathetic and bears him animosity. His mother, who often had to hide him from his father, is a nervous ailing woman of poor intelligence, and he is fond of her. A maternal grandfather suffered from epilepsy, and a maternal uncle died in a mental hospital.

He was a frightened timid child, pampered by his mother, and afraid of getting hurt. His school record was reasonably good, and he worked for a time as messenger and clerk. He is said to have had a happy disposition and a sense of humour before the illness, was a keen reader and fond of company, but indulged in obsessional ruminations and compulsions. From his early years he had almost weekly severe headaches. He had been engaged for several years, but much to his fiancée's exasperation they drifted along—he considered his symptoms a handicap to marriage.

The illness began in 1934 when working on a landing at his place of work. "The whole world seemed to change and people crossing the landing from one room to another seemed to do so with amazing rapidity. No sooner had they come out of one door than they were at the other. Also it seemed to me that the atmosphere had gone dull and darker." This was followed by giddiness, pains in the eyes with spots "floating" in front of them, and coldness of limbs. He complained of a far-away vague and dazed feeling and became preoccupied with "time."

For some years before the onset he had become increasingly tired and overworked in a new job driving a lorry and trailer for long hours, but he had changed to light work and was much more relaxed when the symptoms began. He carried on despite his symptoms but was puzzled, bewildered, and mildly depressed. The pain in his eyes increased in severity, and he developed bouts of giddiness in which he seemed to move round but did not fall or lose consciousness. His headaches became more severe, and he had attacks of trembling, shivering, and coldness. He was also constantly looking at the clock, since he was unable to account for the passage of time.

This condition continued more or less unchanged, but he was not severely depressed till 1937, when the symptoms became more intense. He was then having to take frequent periods of sick leave, and from 1937 to 1940, when he was conscripted into the Army, he had spells of unemployment or casual work, no job lasting longer than three months.

During the excitement of the first year in the Army he felt comparatively well and gained promotion, but with exacerbation of his symptoms he was soon reduced to the ranks and discharged. After a succession of jobs he was admitted to Sutton in April, 1944, in an anxious depressed state. He regarded himself as a failure, and was self-concerned, morbidly introverted, and obsessional.

There was little change after a course of psychotherapy, and on discharge from hospital he attempted numerous jobs in the country, since he was afraid of staying in London because of the flying-bombs. His obsessional thoughts became very insistent, with particular reference to the "passage of time," and he lost weight and remained depressed and drawn.

The feelings of unreality never disappeared entirely since their onset in 1934, though they were slight and did not trouble him at times; but on readmission to hospital in 1946 he had an acute feeling of unreality, a dazed feeling, and a feeling of vagueness which he found very difficult to describe.

Ether abreaction and benzedrine were unsuccessful, and there was no change in his mental state, though he put on weight with insulin. He was then treated with electric convulsion therapy, but after the third treatment he became severely confused and muddled, with an increase of his symptoms of depersonalisation. "Everything seems to have changed. The world is changed and unreal, and I am far away and outside everything. The time seems all wrong, and I can't grasp anything." He bitterly blamed the therapy for the deterioration in his condition.

Again numerous treatments, such as excitatory abreaction under cardiazol and 'Pentothal,' continuous narcosis, and vasodilators, produced little or no change, and he continued to feel dazed and in a fog. Finally he attempted suicide.

Mr. McKissock carried out a prefrontal l June, 1946. Patient refused food for several days operation and was noisy at times. A fortnight later smile benignly and say that his preoperative were worse, though he was obviously improved preoccupied with his previous complaints.

The following week he said he was no longer th the passage of time. "I don't know what made on that at all." Nevertheless, though he was unable any longer, had lost his headaches, stopped writing letters, and was active and cheerful, he said he was no

A well-marked change occurred when he left He lost his unreality feelings, obtained a better job t he had previously held, and married.

Interviewed a year after the operation his wife said happy, interested, and better than when she first since he was "not half so shy." Patient said he was operation was done, and everything seemed fine, th eyes felt slightly heavy and he had an occasional sli ache. The physical change was striking, since his smoothed out and he looked fatter and healthier. doing well in the same job.

This is a case of a chronically obsessional with twelve years' history of depersonalisatic lost his symptoms two months after leucotom personality appears to have improved as a r the operation.

Case 4.—A woman, aged 26, readmitted to hospita tember, 1946, complained that for three years she had persistently from a "blindness of the mind" and an " to visualise."

Her mother is of an anxious disposition and had a breakdown at the age of 28, probably depressive, father died a few weeks ago. Patient is one of the two triplet brothers are well. An older brot postencephalitic personality changes.

She had a happy childhood until the age of 8, w brother developed encephalitis. He became troubles spiteful to her, though she was very attached to hi school record was good despite frequent attacks of "t of the limbs," and she also had a good record at occupations, such as printing and electrical engineerin had been unofficially engaged to a soldier for sever but did not marry, since she considered it her duty after her brother.

Her previous personality is described as that of an o worrying over-conscientious obsessional type with a t to depression and hypochondriasis, but she had many and hobbies. She has a rheumatic valvular affectio hypertension, and a benign fullness of the thyroid.

Early in the war 1939–45 her invalid brother was sibling to remain at home. She was very active, many hours a day, but devoted all her spare time brother and could not dismiss him from her mind; made her life "a living hell with his unsocial nasty tri sneers." She developed a sinking feeling in the sto fear of tuberculosis after a friend in her factory h tracted it, and had recurrent attacks of sweati trembling.

In September, 1944, "something snapped" at "My brother's face came to my mind, and everythi went. My head became a complete blank, and all v my mind went instantly. I looked round and eve seemed unreal." She ran home in a panic and exp fears of insanity. The symptoms persisted, and ov she spent three months in a rehabilitation centre wh received eight electric convulsion shocks and a co modified insulin and narcosis without success.

She was first admitted to Sutton in June, 1945, w described herself as a robot, outside herself and eve and that her head was empty and hollow yet fill thoughts. "When I close my eyes I can *think*, but comes. Familiar things do not *seem familiar* and I meaning. I have to hang on to the feeling as *to* how I feel. Nothing means anything any more." He complaint was *inability to visualise*, and she also com of change in the sense of time. "Time is just a spa Everything is just a blank space. . . . Time is meani She was intensely anxious and agitated, but derived no from psychotherapy, vasodilators, vitamins, amphe epanutin, and narco-analysis.

made efforts to go out and mix after discharge from al; and, though she gained weight and slept better, ense of "blindness" continued. Her thyroid was igated, but no operation was advised, and a further d course of psychotherapy had no effect.

condition deteriorated, and she was readmitted in mber, 1946, feeling desperate, hopeless, and unable to on. She wrote a list of seventeen groups of symptoms, minantly those of depersonalisation, and looked a lonely e of dejection and depression. Among her numerous ptions of her strange and unreal state was the comparison self to "a broken camera with the lens out of focus." itory abreactions under ether were attempted, using umatic experiences of her brother as the trigger stimulus, spite a good deal of emotional release she felt no better. cotomy was done by Mr. McKissock in December, 1946. t was restless, confused, irresponsive, and negativistic veral days after the operation, and had a grand-mal the fourth day. During the second week her mental became clear and she was brighter, said her symptoms s before but did not distress her, showed no initiative, ound her teeth.

continued in the ensuing weeks to insist she was no nt, though she was obviously cheerful, wrote letters he had previously been unable to do, and admitted she ble to cope better with things. She was incontinent veral weeks. Her appetite improved, she was active ward, kept everybody in good spirits, and made many s, whereas previously she sat about all day on her own. ially she volunteered the information that she was ving slowly, but she repeatedly said her mind remained and there was an inability to visualise.

weeks after the operation her father died suddenly, and ok it in an off-hand manner and was "surprised." Her de to her brother has completely altered, and she gets ll with him. "I don't worry about him. I don't worry anything any more." She returned home two months he operation, developed an enormous appetite, gradually er apathy, and found herself a job.

mother said patient was gradually improving, taking interest in herself and surroundings, helping at home visiting friends, and showed no signs of depression. nt's periods became regular for the first time for some

w, eight months after the operation, her mother expresses ude and the patient agrees the operation was well worth , despite the fact that she still cannot visualise. She this in an unconcerned fashion, and it is her only plaint.

his is a case of a chronic obsessional rendered pletely useless by the symptoms of a severe deperlisation state. All symptoms have been relieved he operation *except an inability to visualise, but this* es her no concern. It is only eight months since operation; hence one cannot tell if that symptom will disappear.

ase 5.—A woman, aged 32, admitted to hospital in nary, 1947, complained that a feeling of unreality had denly descended on her like a cloud nearly three years iously and persisted unchanged.

er father is described as normal except for an "obsession" ut making money, and her mother is moody and quickpered. Patient is one of dissimilar twins, and the parental ction was said to have been lavished on her prettier sister. twins got on well together. She had an excellent scholastic rd, and was popular, good at sports, and head girl for two rs.

he became a student teacher, but her career was soon rrupted by a sudden attack of depersonalisation, with ciated phobias, at the age of 18. This lasted nine months, of which she spent as a voluntary patient in a mental pital.

er upbringing at home had been strict, and discussions on were taboo; the attack of depersonalisation followed incident two months earlier, when a man had exposed self to her in a wood. After a spontaneous recovery she remained well for three years, when the symptoms of ersonalisation recurred.

his second attack lasted three years, in the course of which had spells in two mental hospitals. Eight cardiazol vulsions had no beneficial effect. She became engaged during the illness but terminated this later on, and she then experienced considerable guilt over illicit sex relations with a few men.

She married a regular Army officer after recovering from the second breakdown, and they have two children. When well she is said to be energetic, capable, keen on sports and reading, houseproud, conscientious, and liable to phobias.

Patient continued well until 1944, when her husband was posted to India. She was very upset over this; and, after he left, another attack of depersonalisation came on suddenly in the street. "Everything altered and became unreal. A blackness came down, and from that moment everything was centred on self." She became tense, anxious, and depressed, sat about and cried most of the day, and eventually spent six months in a private mental hospital. There she received eight electric convulsion shocks, but without any effect on the feelings of unreality, though the depression eased.

Her husband returned from India in October, 1945, on compassionate grounds; but, since her distress continued, she returned to the mental hospital and had a further seven electric convulsion shocks, again without benefit.

She next received treatment from an unregistered practitioner but had to be admitted to another mental hospital early in 1946, since she felt unable to carry on and was considered suicidal. Here she was given twelve cardiazol fits. The treatment had to be interrupted for a time after the sixth convulsion because of a dislocated shoulder. She left the mental hospital in a pitiful state, visited several consultants, and was finally referred to Sutton.

On admission she had a forced smile, talked freely without retardation, but was preoccupied with obsessional thoughts, mainly of suicide, and most of her conversation consisted of self-accusations and descriptions of her unreality.

Ether abreaction over her fears of insanity and her husband's infidelity before the onset of her illness led to some emotional release without corresponding improvement. Further attempts, using other incidents, also failed.

Her condition deteriorated, despite the fact that she put on 2 st. in weight with modified insulin treatment. She repeatedly asserted that she did everything mechanically, had no feeling, nothing registered in her mind, and she begged for an operation to relieve her suffering, or her suicidal impulses would prove to be too much for her.

Mr. McKissock operated on her on March 3, 1947. She reported an immediate easing of tension. For some days she complained of a headache, appeared drowsy, and said she felt lazy; but, almost as soon as her mental state was clear, she declared that her unreality had gone.

A week after the operation she was cheerful, happy, and free from complications, and said: "I feel normal; everything is real; I could not contemplate before that I could feel well again." She rapidly adjusted to a normal existence, returned to her home in a fortnight, and took over full household duties.

When seen two months after the operation she had returned from an energetic sporting holiday in Switzerland, said she felt fine, had regained her normal weight, and had no problems. Her husband and relations are delighted with the result. This happy state still exists, five months after the operation.

This case of depersonalisation of nearly three years' duration, like case 2, showed an immediate response to leucotomy after exhaustive and intensive alternative methods of treatment had failed.

DISCUSSION

Before the indications and value of prefrontal leucotomy in severe and long-standing depersonalisation can be assessed a larger series is necessary, and the patients will require observation after operation over longer periods than those cited in the case-records. Nevertheless certain facts stand out. The syndrome is not infrequently met with, and, though some patients recover spontaneously, a study of the histories reveals the utter misery experienced. They drift from hospital to hospital, often spending long periods in mental hospitals, and are keenly aware of the abnormality of their symptoms. They also have the utmost difficulty in describing their symptoms and in being understood.

A sufficient indication of the *mental distress* often caused by this crippling disability is shown by the variety of treatments to which the patients submit, and the results obtained with such treatments, as seen in a study of the case-records, only serve to emphasise the difficulty in ameliorating their symptoms. The 5 patients cited have received a total of 25 cardiazol fits and 50 electric convulsion shocks. Convulsive shock therapy is of little or no use; it may temporarily ease the accompanying depression, but the feelings of unreality remain or even become accentuated. In fact, some patients have become depersonalised during electric convulsion therapy, and case 3 became considerably worse after the third electric convulsion shock, and the treatment was discontinued. Of the 5 patients 4 lost their symptoms of depersonalisation after the operation (2 immediately and 2 after several months), and the fifth patient has improved and is still improving. The 2 who recovered immediately had had previous clear-cut attacks of unreality, whereas the other 2 had had a prolonged first attack which seemed to be going on indefinitely.

Though the present series is very small on which to base conclusions, there appears to be a difference in response between the two clinical groups. On the other hand, it may well depend on the position of the incision and the amount of white matter severed at operation.

Psychotherapists and psycho-analysts, such as Schilder (1939) and Oberndorf (1941), have commented on their generally poor results in the treatment of the depersonalisation syndrome. Our patients have not had prolonged systematic psychotherapy, but they have had this form of treatment to the limits of practicability.

A few striking successes have been obtained by excitatory abreaction under ether and more recently by the use of pentothal combined with intravenous 'Methedrine.' Patients, therefore, that might have come to leucotomy have been spared the operation. But this is only an occasional result.

Though there is an abundant psychopathology in the cases here recorded it has had to be omitted in this paper, as also the results of special investigations, such as the Rorschach personality assessments. Intelligence tests carried out before and after operation in all these cases demonstrate that there is no intellectual impairment.

Papers on leucotomy have recently emphasised the deterioration in some personality traits after operation (Hutton 1947). Such patients have usually come from mental hospitals. The findings have been less pronounced and less often met with in the material of this neurosis centre with, generally speaking, patients of comparatively good personality showing little deterioration before operation, and it is this type of case with which we are concerned.

I wish to thank Dr. Louis Minski, medical superintendent, for his kind permission to publish, and Dr. William Sargant for his helpful advice and criticism.

OPERATIVE TECHNIQUE

(Wylie McKissock, M.S. Lond., F.R.C.S.)

The technique used was that described by McKissock (1943) with only minor modifications. Burr-holes are made 3 cm. behind the lateral margin of the orbit and 5 cm. above the zygoma through 2 cm. skin incisions. The openings in the dura are large enough only to expose an area of cortex free from blood-vessels. A brain needle is inserted to a point 0·5 cm. short of the midline, the needle being angulated slightly forwards to avoid the anterior horn of the lateral ventricle. The needle, with stylet withdrawn, is then swept upwards and is, at the same time, introduced more deeply to an extent of 2–2·5 cm. to cut a line parallel with the falx, and finally outwards to divide as much white matter as possible. It is then reintroduced in the original plane, swept downwards until just above the orbital plate, and finally swept outwards across the
to divide most of the white matter in this

of the C57 and A strains were decidedly more sen
to its toxic action than were R III mice. A
difference in the sensitivity of these two strai
colchicine has been observed (Ludford 1947).

The following were the tumours selected for treatm

C57 Low Mammary Cancer Strain, Black Mice

(1) A mammary carcinoma originally induced by
suckling with an A-strain female. This tumour was
adenocarcinomatous type. The 18th-generation trans
were used.

For comparative purposes the growth-rate of this tu
has been arbitrarily chosen as unity (fig. 1). The figu
parentheses after each of the other tumours listed
gives approximately its comparative rate of growth.

(2) A squamous-celled carcinoma ($1^{1}/_{2}$) which arose
taneously. The 13th-generation transplant was used. A
stage sections exhibited very little keratinisation.

A-Strain of Strong with High Incidence of Mammary
Lung Cancer, Albino Mice

(3) A carcinosarcoma ($2^{1}/_{2}$) which originated spo
as a mammary carcinoma. During the course of serial
plantation the stroma underwent sarcomatous transf
and both sarcomatous and carcinomatous elements
throughout subsequent transplantations (Ludford and D
1944, 1945). The 31st-generation transplants were used.

Histologically the tumour consisted of compact ma
carcinoma cells surrounded by sarcoma cells forming a
cellular stroma.

(4) A polymorphic-celled sarcoma ($2^{1}/_{2}$) which ori
by the sarcomatous transformation of the stroma of a
mary carcinoma. The 26th- and 55th-generation tran
were used.

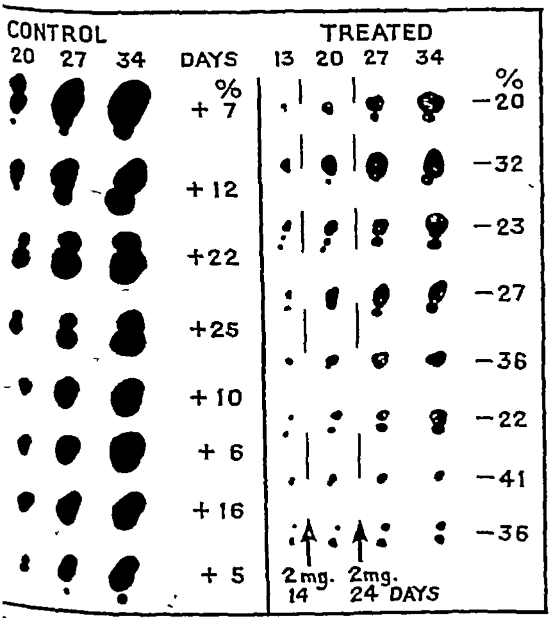
RESULTS

e of these tumours exhibited a specific sensitivity bœstrol treatment. Dosages which did not impair alth of the mice had no appreciable action on the f growth of the tumours. Tumour growth was ted only in mice suffering from the toxic action lbœstrol, which was accompanied by considerable f weight. Below are given the protocols of two ments illustrating the general results of this tigation.

ment Demonstrating Inhibition of Tumour Growth Toxic Doses of Diethyl-Stilbœstrol

mmary carcinoma no. 1 was transplanted into the ank of 16 mice of the C57 black strain. Fourteen later a 2 mg. pellet of diethyl-stilbœstrol was ed into the right flank of 8 of the mice, and a r dose was administered again on the 24th day. mouse was weighed every time the tumours were ed. Fig. 1 shows the rate of growth of the tumours, he figures after the last charting give the percentage gain (+) or loss (−) in weight since the first charting on the 13th day. From fig. 1 it is obvious that there was a considerable inhibition of tumour growth in the treated mice, but this was accompanied by a great loss of weight. The mice were extremely emaciated, and most of them ultimately died.



1—Inhibition of growth of mammary carcinoma in C57 mice by toxic doses of stilbœstrol.

It was repeatedly observed during this investigation that, though tumour growth was inhibited when animals became ill, their tumours began to grow again at the normal rate if they recovered. Sections of tumours from treated animals such as those charted in fig. 1 exhibited no specific degenerative changes. There were very few mitoses. A greater proportion than usual were metaphases, suggesting some delay in anaphase separation of the chromosomes. There was no indication of a specific mitotic poisoning of the type induced by colchicine.

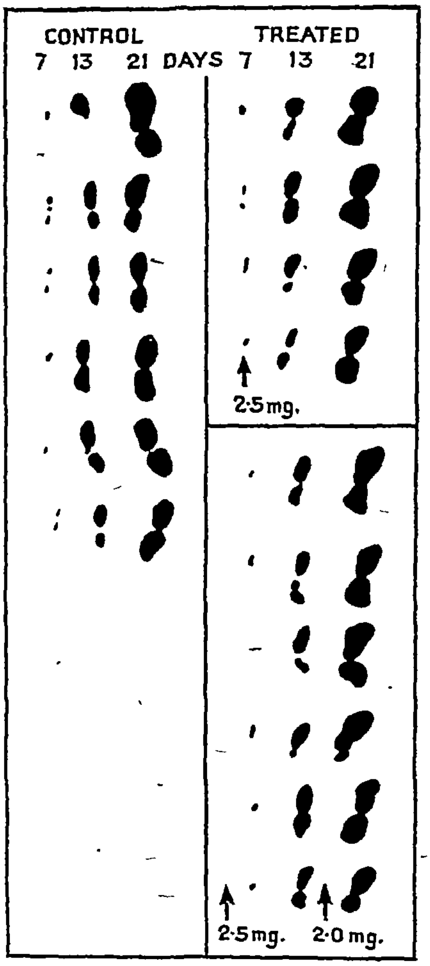


Fig. 2—Non-inhibition of growth of mammary carcinoma in R III mice by stilbœstrol in the absence of toxic symptoms.

Experiment Demonstrating that Diethyl-Stilbœstrol does not Inhibit Tumour Growth in the Absence of Toxic Symptoms

Mammary carcinoma no. 7 was grafted into 16 mice of the R III strain, of which 6 were kept as controls and the remainder received 2·5 mg. pellets of diethyl-stilbœstrol on the 7th day; 6 of these received a second pellet of 2 mg. on the 17th day. Fig. 2 shows there was no inhibition of tumour growth. All the mice increased in weight, and the average gain in weight of each of the three groups was about the same. It will be observed that 6 of the mice in this experiment received 0·5 mg. of stilbœstrol more than the C57 black mice of the other experiment (fig. 1). Yet the R III mice tolerated this larger dose without the appearance of toxic symptoms. Obviously, genetic constitution is an important factor in determining sensitivity to stilbœstrol.

It has been reported by Lettré (1943) that diethyl-stilbœstrol applied to tissue cultures of chick fibroblasts in a dilution of 100 µg./ml. has a mitotic poisoning action similar to that of colchicine. The photomicrographs illustrating Lettré's paper show numerous rounded cells in treated cultures, but it is impossible to distinguish whether these are arrested mitoses or "resting" cells which have become rounded off in the presence of a toxic substance. We therefore considered it desirable to carry out some experiments with tissue cultures to see if results comparable with those induced by colchicine could be obtained with stilbœstrol.

Lettré dissolved the stilbœstrol in alkaline solution, whereas we dissolved it in liquid paraffin and also used colloidal solutions. We had the further opportunity of testing a water-soluble phosphate derivative for which we were indebted to Prof. E. C. Dodds, F.R.S. Various concentrations of each preparation up to lethal dosages were applied to cover-slip cultures of embryonic and mammary-tumour tissue (mouse carcinoma 63). No indication was obtained of a specific action on the cancer cells, and no mitotic poisoning action was seen comparable with that of colchicine or its active derivatives.

DISCUSSION

This investigation was not carried out with the idea of contributing in any way to our understanding of the mode of action of stilbœstrol on prostatic cancer. We were concerned with the wider question, whether stilbœstrol has a specific action on the growth of malignant cells as such, either in vivo or in vitro. On the tumours used in these experiments stilbœstrol exhibited no specific inhibition of growth. Such inhibition of growth as took place with relatively high dosages was the result of a non-specific toxic action.

Further, our results do not confirm Lettré's (1943) contention that stilbœstrol has the same kind of mitotic poisoning action as has colchicine. Colchicine has a dual action on tumours: (1) it brings all cell division to a standstill at the metaphase by preventing the formation of the mitotic spindle (colchicinic mitosis); and (2) it induces hæmorrhage in rapidly growing tumours. Evidence has been adduced that such inhibition of tumour growth as can be induced by colchicine is primarily the result of hæmorrhage (Ludford 1947). In our experiments with stilbœstrol the characteristic cytological action of colchicine was absent, and a degree of intratumoral hæmorrhage sufficient to lead to tumour regression was never induced. There is no justification for including stilbœstrol in the same class of mitotic poisons as colchicine and sodium cacodylate, which both have such a pronounced action on the mitotic spindle (Ludford 1936).

SUMMARY

The action of diethyl-stilbœstrol has been investigated on ten different transplantable mouse tumours in mice of four inbred strains (C57 black, Strong A, R III, and C3H). These tumours included different types of mammary carcinomas: a carcinosarcoma, a squamous-celled carcinoma, a lung carcinoma, and two sarcomas.

On these tumours stilbœstrol showed no specific inhibition of growth; such inhibition of growth as took place with relatively high dosages was the result of a non-specific toxic action.

Neither in vivo nor in vitro did stilbœstrol induce the same type of mitotic poisoning action as does colchicine.

Genetic constitution is a significant factor in determining sensitivity to the toxic action of stilbœstrol.

We are indebted to Prof. W. E. Gye, F.R.C.P., F.R.S., for helping us to complete this investigation, which was begun when we were members of his staff.

AUSCULTATION IN ACUTE ABDO DISEASE

C. G. ROB
M.C., M.A., M.Chir. Camb., F.R.C.S.
SENIOR ASSISTANT, SURGICAL UNIT, ST. THOMAS'S H
LONDON

DURING the war surgeons came to regard ab auscultation as a very important part of the examination of a patient with an abdominal for often morphine had minimised signs tenderness and rigidity. In civilian practice, auscultation is commonly omitted from an a examination.

In the "acute abdomen" auscultation is showing whether peristalsis is present or not fluid splash of distended loops of intestine mo respiration must not be confused with the so peristalsis. The splash can be reproduced by ro patient and listening at the same time. With ex there is no difficulty in differentiating the two

If the sounds of peristalsis are heard over the abdomen, further auscultation is unnecess they are locally or entirely absent, further is required. The absence of sounds cannot immediately; auscultation should be done for 2 or 3 minutes at a time until the presen of peristalsis has been confirmed beyond the normal abdomen may be silent for periods.

RESULTS

The results of such auscultation in 250 an acute abdominal catastrophe, and in 15 of the abdomen, are given in tables I an figures show that auscultation is of little early case of acute appendicitis, but of help once a local or general peritonitis ha Silence on abdominal auscultation is patho peritonitis, though it is of less value in the di of its cause. The following case illustrates the of abdominal auscultation in such patients:

TABLE I—FINDINGS ON ABDOMINAL AUSCUL
250 CASES OF ACUTE ABDOMINAL DIS

Diagnosis (established at operation)	No. of cases	Peristalsis present over whole abdomen
Acute appendicitis without perforation	124	114
Local peritonitis (perforated appendix, leaking peptic ulcer, &c.)	36	10
Pelvic peritonitis (perforated appendix, salpingitis, &c.)	14	1
General peritonitis (perforated peptic ulcer, perforated appendix, &c.)	36	0
Intestinal obstruction without strangulation	16	16
Intestinal obstruction with strangulation	12	7
Hæmoperitoneum (ruptured ectopic gestation, ruptured spleen, &c.)	6	6
Intraperitoneal rupture of urinary bladder	3	3
Acute hæmorrhagic pancreatitis	2	0
Bile peritonitis	1	0

A young police constable was admitted wi history of generalised abdominal pain. On exa abdomen was rigid and tender. A perforated peptic vas suspected, but abdominal auscultation revealed lsis in the epigastrium and silence in the hypogastrium. d to a diagnosis of perforated acute appendicitis, which nfirmed at operation.

his patient the information obtained by abdominal tation enabled the incision in the abdominal wall ocated correctly.

stinal obstruction without strangulation produces t increase in peristalsis. Once strangulation has place, however, sounds of peristalsis may disappear. of particular interest if the cause of the strangula- not an external hernia. The present series includes patients with a complete absence of abdominal lsis. In these patients abdominal auscultation in deciding whether intestinal strangulation has place, which is of great importance now that a onservative attitude to simple intestinal obstruc- customary. The following case illustrates this

LE II—FINDINGS ON ABDOMINAL AUSCULTATION IN 150 ABDOMINAL WOUNDS [1]

n of hollow viscus	Peristalsis present	Peristalsis absent over whole abdomen
.. ..	6	92
.. ..	51	1

ldier was admitted with 18 hours' history typical of nal obstruction due to adhesions from an old abdominal . Peristalsis was increased, and he was treated by nal suction and intravenous saline, followed by recovery. before his discharge from hospital a second attack ped. This time his pain was continuous and his abdomen with complete silence on auscultation. Intestinal ction with strangulation was diagnosed and confirmed ration, when a volvulus of the small intestine was and the strangulation was relieved.

uncomplicated hæmoperitoneum was present in r wounds and 6 other patients in the present series. ery case sounds of peristalsis, though sometimes were heard—a very valuable aid in the differentiation is condition from peritonitis. An intraperitoneal re of the urinary bladder was found to be the only abdominal lesion in 5 war wounds and 3 other nts, and again sounds of peristalsis were heard in one. Acute hæmorrhagic pancreatitis, or free bile e peritoneum, has produced complete silence on ltation.

ring convalescence the first return of peristalsis a period of silence is a point worthy of note, because often the first indication that gastric or intestinal on may be discontinued.

SUMMARY

250 patients with an acute abdominal emergency, 150 patients with an abdominal wound, abdo- l auscultation has provided valuable diagnostic

e absence of peristalsis can only be established by and repeated periods of abdominal auscultation.

this series intestinal peristalsis was abolished by presence, in the peritoneal cavity, of intestinal ents, pus, bile, hæmorrhagic exudate from strangu- l intestine, and exudate from an acutely inflamed reas. It was not abolished by the presence of blood urine in the peritoneal cavity.

nfirmed silence on abdominal auscultation, whether or general, is a positive sign of peritonitis and a able aid to the diagnosis and localisation of an acute minal lesion.

RUPTURE OF RECTUS ABDOMINIS MUSCLE DURING PREGNANCY

REPORT OF TWO CASES

JOYCE MORGAN
B.Sc., M.D. Lond., M.R.C.O.G., D.A.
OBSTETRICIAN, HILLINGDON COUNTY HOSPITAL, MIDDLESEX

SPONTANEOUS rupture of the rectus abdominis muscle is a rare complication of pregnancy, usually undiagnosed before operation, though the signs and symptoms are so constant that diagnosis should be easy.

Torpin (1943) collected 27 cases published since 1900 and added 1: 25 were in multigravidæ and 3 in primigravidæ; and 15 occurred after the strain of severe coughing, 5 during that of labour, 2 after a fall, and 1 during labour complicated by typhoid fever. In 5 cases the history was incomplete. There were 4 deaths: 2 from hæmorrhage and shock, 1 from postoperative pneumonia, and 1 in which the cause was not stated. The earliest cases occurred at 18 weeks' pregnancy. In 3 early cases the patients aborted, and there were 4 stillbirths. In 4 cases the condition was diagnosed and treated conservatively; all these patients recovered. Blood-clot was evacuated in 17 cases, 2 of the patients also having cæsarean section. After this method of treatment 2 patients died, 2 aborted, and 9 recovered; in 4 cases the result was not stated. In 1 case treatment was by cæsarean section only, and the patient recovered.

Of 2 cases reported by Fahmy (1944) the first was treated by evacuation of clot and the pregnancy continued to term; and in the second a small swelling below the right subcostal margin was at first diagnosed as acute cholecystitis and subsided without treatment.

Thomas (1943) reported 1 case which he diagnosed as concealed accidental hæmorrhage and treated by rupture of membranes, followed by application of Willett's forceps, and finally by cæsarean section, two pints of blood-clot in the right rectus muscle being evacuated incidentally. The patient recovered. Thomas (1945) summarised Torpin's (1943) cases and published a further case. This patient was diagnosed on admission to hospital and was at first treated conservatively. Bleeding increased during rest and necessitated operation, at which it was found that the bleeding was from a branch of the deep epigastric artery, which had to be ligated. The patient came into labour spontaneously a few days later and was delivered of a stillborn infant. She made an ultimate recovery.

Dawson (1944) reported 1 case, which was treated by cæsarean section, the hæmatoma being left to subside. This patient also made a good recovery.

The present cases may be of interest to add to the list.

Case 1.—A woman, aged 41, who had had one previous pregnancy in 1938, associated with "kidney trouble," but terminating in a normal delivery of a healthy infant weighing 6 lb. 4 oz., was first seen at the clinic on Aug. 10, 1946. Her last monthly period had been on May 10, 1946.

On examination: a pale woman in poor general condition, breathless on exertion. Heart and lungs normal. Blood-pressure 166/108. Abdomen soft. Uterus just palpable above symphysis.

Investigations.—Blood-count: red cells 4,550,000 per c.mm., Hb 94%, colour-index 1·0. Urine: no red cells; a few leucocytes; no casts; many gram-positive cocci; no albumin. Intravenous pyelography showed calcified abdominal glands; anatomy and function of each kidney normal.

Patient was admitted for rest, and at the end of a week the blood-pressure fell to 130/90. She was regarded as a case of essential hypertension, and was seen every month at the antenatal clinic. Her blood-pressure remained about 140/100 until the thirtieth week, when it rose again to 160/110. At this stage the patient developed a severe attack of bronchitis and was in bed at home for a fortnight.

specific therapy. He lays greater stress on the signs which the ordinary clinician can elicit than on those special tests, such as estimation of the vitamin content of the blood, which are available only to the expert.

Principles of treatment are fourfold: conditions such as infections and hyperthyroidism, which increase the nutritional requirements, are alleviated or removed; any coexisting disease is treated; a liberal diet is prescribed; and, since such diets often cannot be consumed in the early stages of treatment, supplements of vitamin and yeast preparations are given. In this way, all the patients were improved to an extent which allowed them to resume work.

Dr. Gordon's book is a fine concise account of clinical nutrition for the practitioner. It describes the great advances in knowledge made in this young science and critically appraises the many beliefs based on less certain evidence. No-one reading this book will have any doubt as to which diseases warrant nutritional therapy and which will react disappointingly. There are first-class descriptions of the mode of action, results of deficiency, and indications for giving supplements of the vitamins and mineral elements, and of the rôle of protein, carbohydrate, and fat in the diet. Additional chapters describe the basis of weight control; the influence of nutrition on dental caries, and the economic aspects of nutrition. The book is fortunately not burdened with detailed tables of the composition of foods, though there is an appendix which contains as much of such information as would ever be required by the practitioner.

Electronics and Their Application in Industry and Research

Editor: BERNARD LOVELL, PH.D., F.INST.P., physical laboratories, University of Manchester. London: Pilot Press, 1947. Pp. 660. *42s.*

THIS book will be very welcome to those who try to keep abreast of electronic applications either in laboratory work or industry or medicine. The chapters on electronics in medicine (Grimmett), electronics in physiology (Pumphrey), the betatron (Craggs), and electron microscopy and electron diffraction (Cosslett), are of interest to doctors, and are written by people who have all made significant contributions to their subjects.

Grimmett demonstrates his detachment when he says: "Radiotherapy is only a passing phase in cancer treatment, in the sense that it must sooner or later give place to biological methods of treatment. . . . The future may well show that the truly valuable contributions to medical science in this field are rather to be found in the fundamental knowledge which is being gained of the ultimate nature and structure of the cell." Pumphrey shows what a new era opened to physiology when the almost inertia-less electron became the prime recorder of electrical impulses. It is to be hoped that instrument-makers will note that "there is literally no equipment available for reproducing or recording sound in the range of 10–100 Kc./s." The first betatron to reach this country was operated at 4 M.e.v., but the article on this electron accelerator describes in some detail the construction of an instrument operating at 100 M.e.v. What the electron has done for vision is described by Cosslett with the aid of a superb set of photomicrographs taken by means of the electron microscope. Bacteriophage is here visible, in support of the imaginative flight of the French bacteriologists of a former decade.

Dr. Lovell, chief editor of the book, could hardly have selected his authors with more felicity.

The Child from Five to Ten (2nd ed. London: Hamish Hamilton. 1947. Pp. 475. 18*s.*).—This is a sequel to Dr. Arnold Gesell's earlier work, *Infant and Child in the Culture of Today*, and he has had the collaboration of Dr. Frances L. Ilg in writing it. Though it was compiled in the Yale clinic of child development, where so much careful observation has been put on record, the material is thin and much of it banal. The style can be illustrated at random: "EIGHT is coming out from his more serious, thoughtful inward self of SEVEN. Indeed, this new outer self seems to want to be constantly contacting people, going places, and doing things." "He may still have a lingering fear of the dark, and is said to be leery or shy of the dark." And so on. A general atmosphere of whimsy about the presentation, the illustrations, the tions, and the use of exclamation marks is likely to le English reader cold. There may be a place for a book of kind, but hardly on the busy practitioner's bookshelf.

RETRACTOR FOR OPERATIONS ON NUCLE PULPOSUS

THE retractors illustrated here have proved satisfactory in operations on the nucleus pul They are modifications of the original idea described Taylor,[1] and their principle is to use a fixed bony on the skeleton as a fulcrum against which le can be exerted to retract the superjacent muscle.

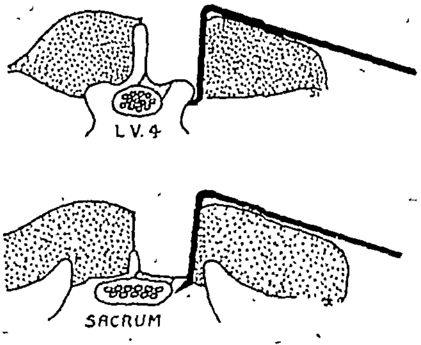

Fig. 1—Above: the retractor with two blunt hooks, used to ret muscles from the spine above the level of the sacrum. Below retractor with a single sharp hook, used to retract the musc lying the sacrum. The spike is hammered into the bone with a

are most suitable for laminectomy in the prone p *when they can be rendered self-retaining* by att. weights to their handles with sterile chains or ba

Experience has shown that two shapes of retract advisable in the exposure needed for hemilaminect One of these retractors (fig. 1 above) is provided with blunt hooks; this can be hooked under the bones of the vertebræ lateral to the posterior articulations, at the level of the 3rd, 4th, or 5th lumbar vertebra. The other retractor (fig. 1 below) is provided with a single sharp hook; this is required for retraction of the muscle superjacent to the sacrum, because at this site it is impossible to reach any lateral bony ridge under which a blunt hook could be lodged. At this site the spiked retractor is passed under the muscle and the term *spike is driven into the smooth posterior* surface of sacrum by a few blows with the mallet; the handl the retractor can then be depressed in order to ret the muscle (fig. 2). In this position both retractors be rendered self-retaining by means of sterile cord chains attached to the handle at the end of which a wei of about 3 lb. is secured. These retractors appear assist hæmostasis during operation by the const tension they maintain on the muscle.

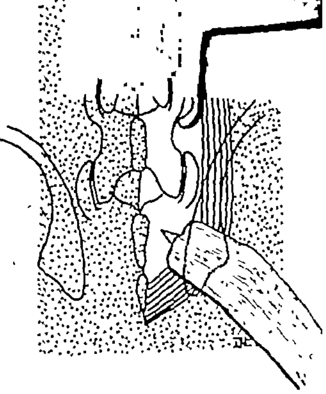

Fig. 2.—The two retractors in place.

They are made by Messrs. Down Bros. and Mayor & Ph Ltd., of London.

Leading thoughts on CHILBLAINS

. . . remembering last winter's high incidence of chilblains not only among chronic cases but in many first sufferers . . . considering how best to protect chronic sufferers from the same cause and effect this winter . . .

These thoughts lead to the effective *prophylactic* measure that Colloidal Calcium with 'Ostelin' provides. Three to five injections of this colloidal solution of calcium and vitamin D are normally sufficient to see the patient safely through the winter. If the tendency to chilblains persists, a further reinforcing course should rapidly restore the circulation in the skin capillaries to normal. Injections are painless and the course is inexpensive

GLAXO

COLLOIDAL CALCIUM with 'OSTELIN'

0.5 mg. colloidal calcium ; 5,000 i.u. vitamin D per cc.
1 cc. Ampoules in boxes of 6, 12 and 100 30 cc. bottles.

‘MYANESIN’

The new muscle relaxant

NOW AVAILABLE

Clinical trials, involving its use in over a thousand cases, have clearly shown the value of ‘Myanesin’ for relaxation of the abdominal musculature during surgical operations.

‘Myanesin’ was discovered in the B.D.H. Research Department. It is an entirely synthetic substance of known and constant chemical composition [$\alpha : \beta$ - dihydroxy - γ - (2 - methylphenoxy) - propane].

‘Myanesin’ is now available as a 10 per cent. solution in ampoules of 10 ml. issued in boxes of 3 and 12 ampoules.

Punishment and Reform

the new Criminal Justice Bill does not do all students of criminal psychology might wish, it rtheless does much; and it opens the way to er advances. Its general object is "to improve methods of dealing with persons found guilty of ces, including adolescent offenders and persons commit repeated offences." An early clause ves the legal distinction between imprisonment penal servitude: "hard labour," which originally nt labour at the crank and the treadwheel, is go, and the various prison "divisions" are to ppear. All sentences will become sentences of risonment, and during his stay in prison the nder will experience the sort of treatment—so it ntended—most likely to help him to reform. chance of reformation will be extended, within ts, to persistent offenders, for whom two types of ence are proposed: young adults with two ious convictions for serious offences may be ed corrective training for a period of not less n 2 and not more than 4 years; but those over 30 have had at least three such convictions, and se reform is considered unlikely, may be ordered, the protection of society, 5–14 years' imprisonment. power of the courts to pass sentences of corporal ishment is to be abolished, though this method is be retained for dealing with certain serious prison nces. The Cadogan Committee's figures consively demonstrated that corporal punishment does deter, and that its effects are the opposite of rmative; and in the face of this plain evidence abolition will hardly be opposed, unless by persons ayed by subconscious motives.

The sections of greatest interest in the Bill are those lating to young offenders. At present those over are sent to prison when remanded or committed trial; but the Bill proposes that State remand ntres should be set up where people of 14–21 may retained for this period. A court of assize or arter sessions will no longer be able to sentence a rson under 15 to imprisonment (the age is now 14): nd a court of summary jurisdiction will not be able imprison a person under 17. No court is to sennce anyone under 21 to imprisonment unless there ppears to be no other way of dealing with him; ed, if experience justifies these experiments, provision made for raising the age at which a prison sentence ay be received, and to prohibit, by Order in Council, he sentencing to imprisonment by summary courts persons under 21. Furthermore, new institutions, nown as detention centres, are proposed, to which eople between 14 and 16 may be sent for 3–6 months. They are to be set up gradually throughout the ountry, and will provide an alternative to prison for he young offender who does not need training in an approved school or borstal, but whose offence is beyond the scope of a fine or a probation order. It is thought that in such cases a short period of brisk discipline and hard work may prove a deterrent.

The probation system, which has long proved its worth, is to be amended and simplified. The binding-over procedure is replaced by power to discharge an offender subject to the condition that he commits no offence for 12 months. In order that young offenders may be properly impressed with the gravity of probation, the Bill proposes that a conviction shall be recorded in every case before probation begins; but probationers, whether juvenile or adult, are still to be exempted from legal disabilities attaching in after life to a conviction. The minimum period of probation is to be a year. State financial help is proposed for probation homes (in which offenders are given resident training) and probation hostels (from which offenders go out to work daily). Such homes and hostels are at present all run by voluntary societies; the courts have power to require an offender to live in one while he is on probation, and the influence has proved valuable. The Bill proposes that the State shall maintain some homes and hostels of the kind; and that a sufficient number of probation officers shall be appointed for every area, as well as a woman officer for every petty sessional division. The plan, adopted in 1936, of admitting offenders up to the age of 23 to borstal institutions has not proved a success and is to be ended. Many of these older offenders are married, with children, and no doubt the method of treatment was hardly suited to their outlook and responsibilities. Provision is made, however, for the release on licence of young offenders sentenced to a term of imprisonment.

Some new arrangements are made for the care of mental cases. At present courts of summary jurisdiction can get a medical report on the mental condition of an offender by remanding him to prison; but the Bill provides that an offender can be remanded on bail with a provision that he submits to medical examination. If an offender is certifiable as insane the same courts are to have power to make an order for his reception in an institution for persons of unsound mind. The term "criminal lunatics" is to be replaced by "Broadmoor patients," and the responsibility for "Broadmoor institutions" is to be transferred to the Board of Control; though the responsibility for the discharge of their patients will remain with the Secretary of State.

The Government have not decided whether the time has come to reconsider the death penalty, and the decision here will be left to a free parliamentary vote. Another question that should be raised in debate is the need for change in the law dealing with homosexual offences, which is conspicuously archaic. Dr. EDWARD GLOVER[1] has indicated the legal injustice to which such patients are at present exposed; and Dr. ALEX COMFORT[2] has lately suggested the lines which such new legislation might follow. There is certainly room for discrimination between, in Dr. COMFORT's term, "the constitutional invert who conducts himself decently," and the type of homosexual offender who is a danger to others, because he is capable of sexual assault, the seduction of minors, or conduct offensive to public decency.

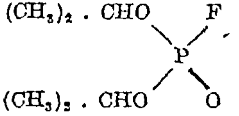
D.F.P.

ONE of the many compounds developed under the impetus of war is di-isopropylfluorophosphate (D.F.P.), which, though chemically unrelated to physostigmine or 'Prostigmin,' inhibits the cholinesterase of serum, red cells, muscle, and brain. Alkyl esters of fluorophosphoric acid were known in 1932 as substances forming toxic vapours capable of causing laryngeal, respiratory, and visual disturbances. But it was not until 1941 that MCCOMBIE and SAUNDERS[1] prepared D.F.P. and found it to be lethal if inhaled. ADRIAN et al.[2] and American workers observed that it is an *inhibitor of cholinesterase, and that this inhibition is permanent* and irreversible, whereas that produced by physostigmine is temporary and reversible and also less potent.

A colourless oily liquid with a specific gravity of 1·055 and a solubility of 1·54% in water at 25°C, D.F.P. has the structural formula:



In aqueous solution it is unstable, undergoing half-hydrolysis in 16 hours. For clinical use it may be prepared as a 0·1% or 0·2% solution in peanut oil; this may be autoclaved and retains its potency for at least a year. In this concentration it has no local irritant effects when injected intramuscularly or applied to the eye. It is moderately volatile and has little smell even at toxic concentrations. Since it is only slowly detoxified, those who have been exposed to the vapour should avoid it for several weeks afterwards, even though only mild symptoms may be produced, such as pupillary constriction, chest pains, nausea, or diarrhœa.

Like physostigmine, D.F.P. inhibits both true cholinesterase and pseudo-cholinesterase,[3] but it is true cholinesterase that hydrolyses the acetylcholine released *at nerve-endings, and it is therefore the degree of this* inhibition which is significant for correlation with pharmacological action. The pharmacological effect of D.F.P. is related to the inhibition rather of red-cell cholinesterase than to that of serum or tissue esterases. It differs from prostigmin, and resembles physostigmine, in being a central excitant; *after intravenous or intrathecal injection the knee-jerk is enhanced, but the most striking effect is on the after-discharge, which is increased and prolonged. It probably facilitates excitatory* transmission in the cord and brain-stem.[4] Intoxication may manifest itself by both *muscarine-like* effects (miosis, bradycardia, salivation) and a *nicotine-like* effect (fasciculation of skeletal muscles). In animal experiments magnesium and calcium have afforded protection against the nicotine effect; small doses of physostigmine, administered before treatment, give added protection, but when they are administered after treatment the toxic symptoms are enhanced. Animal experiment indicates that D.F.P. is much less effective than prostigmin in antagonising curare.[5] *Investigations have been extended to man*, in whom it has been tried in myasthenia gravis, glaucoma, and postoperative paresis of the intestine. *effective ratio of intramuscular to oral* *about 1 to 4.* The administration of 2–3 mg. *muscularly decreases plasma and erythrocyte* *terase, and since the action is irreversible,* even *a single dose the plasma esterase* does not re *normal for several days or even weeks.* Large doses may produce gastro-intestinal sympt increased peristalsis, vomiting, diarrhœa—d *stimulation of the parasympathetic* system. myasthenia gravis D.F.P. has proved less than prostigmin; but COMROE and his ass suggest that, with its prolonged action, it useful as a supplement to prostigmin, dimi fatigue when the patient first awakes. GAD WILSON[7] found that 0·1–10·0 mg. intramus caused no immediate relief of weakness, diplopia, or dysphagia; but there was some im ment in patients given 0·5–2·0 mg. daily for months. Applied to normal eyes, D.F.P. has nounced and prolonged miotic effect, producin myopia and a decrease in intraocular tension; may be spasm of accommodation, visual blurrin ciliary pain. It is about five times more poten persistent than physostigmine; and it can ove the effects of atropine and homatropine on pup *ciliary muscle. In concentrations of 0·05 to* which are non-irritant, it usually lowers the intra tension of glaucomatous eyes even where piloc and physostigmine have failed.[8] It has no direct on the iris muscle. On the gut D.F.P. exerts a po stimulant action, with increase in the tone, and amplitude of contractions; this can be abo by atropine. In postoperative *paralytic ileus* said to be more effective than prostigmin or pos pituitary extract.[9] The drug appears to ha promising future both in therapeutics and fo light it may throw on the mechanism of neuromu transmission.

Our Hospitals

THE shortage of nurses has perhaps obscure *fact that we are also short of hospital buildings* between the two world wars Britain, unlik United States and the Scandinavian countries, u took no large programme of hospital constru In last week's Chadwick lecture Dr. C. T. MAIT a principal medical officer of the Ministry of H showed that these two shortages are closely rel *no less than half of the recently approved ho* rebuilding plans have been concerned with improvement or extension of nurses' homes.

MAITLAND suggested two means whereby the of these shortages may be lessened: (1) a full outpatient departments, and (2) careful classific according to their needs, of patients admitte treatment. The outpatient department, pro used, hastens investigation and spares hospital and he pleaded particularly for the preservation "*the tragedy of hospitalisation*" of children, whenever possible, should be treated at home. *commended the example of a hospital in Midd* where each year 11,000 inpatients are received

)0 new cases are seen in the outpatient depart-
t; in another hospital only 7% of medical out-
nts and about 25% of surgical outpatients are
d to require admission. In the staffing of out-
nt departments MAITLAND believes that general
icians and general surgeons should be brought
he fore, though they should be able to call on
al knowledge or techniques. Science, he reasons,
be matched with humanism, and humanism
short shrift where there are many separate,
ly specialist clinics. Again on humanistic grounds,
emphatic about the maximum number of beds
e hospitals; in their design they should respect
nity of medicine by including a department in
of the major specialties; but lay, medical, and
ng personnel should not be asked to supervise a
tal with more than 500–750 beds, even though
er number may be administered with equal ease.
is a welcome plea, particularly if it takes
iatry within its compass. As for the special
itals, he pointed out that in large centres such as
lon these were founded at a time when surgeons
physicians in new branches, in peril of being over-
e by the main stream, withdrew to evolve their
ial techniques. The peril is now past; and, rightly
ending that continued detachment is harmful,
TLAND would bring them back into the community
he general hospital. He allows, however, there
be a case for the separation of maternity.

ith an eye to economy in skill he proposes that
e needing active treatment should be separated
others who require only maintenance. This
ept is in fact followed in some hospitals caring for
aged sick, notably the West Middlesex; but his
her proposal—that recovery wards should be run
ssociation with wards for the acutely ill—is more
l Such an arrangement would undoubtedly be
omical; but implying, as it would, the transfer of
ents from one ward to another, it cannot be said
romote the mental comfort of the patient that he
s to foster. This consideration is perhaps less
ortant with patients admitted for diagnosis if
r stay is likely to be short. We are all familiar
the patient who, simply because a particular
stigation demands his presence in hospital, takes
a bed which might otherwise be occupied by an
ely sick man or woman. To avoid this there is a
ng case for setting up a special investigation ward
lose geographical and administrative proximity to
outpatient department, where patients, until their
harge or admission to the hospital proper, would
e dormitory accommodation, with food provided,
a help-yourself plan, in a nearby dayroom.

AITLAND argues against vested interest in hos-
ls; despite their emotional appeal, "bigger and
er" hospitals should not be the prime objective
he new service. Pride of place, he thinks, should
rather to the public-health branch. Meanwhile
pitals, handicapped by shortages, will pass on a
y load to the local health authorities which are
onsible for the patient after his discharge. Here
attaches great weight to a close nexus between the
pital management committee and the local health
hority; and he casts the hospital almoner for the
of liaison officer. For the operation of the service
whole he pointed to JOHN STUART MILL's dictum
power at the periphery: wisdom at the centre."

Annotations

NEGOTIATION

As already explained, discussions between the medical profession and the Ministry of Health on the National Health Service Act have so far been conducted by subcommittees of the Negotiating Committee meeting officials of the Ministry. A meeting between the full Negotiating Committee and the Minister himself was arranged for Nov. 11 and 12; but this has now been postponed, at Mr. Bevan's request, until Dec. 2 and 3. The postponement will enable him to make a closer study of the document he received from the Negotiating Committee on Nov. 7, in which they present their observations on a number of disputed issues affecting general practice. Before members of the profession are asked to reach any decision about participation in the service, they will receive a larger document which will contain the committee's observations on all the subjects under discussion, and the Minister's replies to any criticism of his proposals.

PATIENTS AS SANATORIUM NURSES

EX-PATIENTS are now fairly often engaged as sanatorium nursing staff; and on another page Dr. Watt and Miss Sheehan describe a successful scheme of the kind at the King George V Sanatorium, Godalming. Elsewhere Dr. Kissen [1] has told of a less satisfactory experience at Bellefield Sanatorium, Lanark, where a process of continuous reablement of selected patients was attempted.

Five two-bed side-rooms of a ward (closed owing to lack of staff) were converted into three double bedrooms, a sitting-room, and a dressing-room, for six patient-nurses, each of whom was provided with a rest chair. Meals were taken in the main nurses' dining-room—Dr. Kissen does not say whether with the rest of the staff or separately. It was intended to transfer each batch of six patients to the nurses' home as each fresh group of six was recruited. At the start they were engaged for a 24-hour week with a 4-hour day, the duty periods being in the morning, afternoon, and evening of successive days; they were not asked to take night duty. Later it was found possible to increase the hours to 36 a week with a 6-hour day, sometimes broken by a long rest-period. The patients were paid at the rate of student nurses for the hours actually worked, and this very low rate of remuneration —for a 24-hour week they got 11*s*. 8*d*.—was one of the chief causes of failure; for most of the girls lived in Glasgow, a half-crown return journey away; and had they chosen to go home for convalescence instead of working they would have received the basic tuberculosis allowance of 25*s*. a week.

Nevertheless 11 girls took part in the scheme, including 2 from another sanatorium. Their lesions were inactive, and they were all free from symptoms and had been up all day and on graduated exercise for some time. Most of them spent a week or two at home before beginning work. They were warned thoroughly about the proper use of leisure, but only 4 seemed to take the warning to heart; most of them spent much time at entertainments in Lanark and Glasgow, and their long off-duty times—put to such improper use—roused the resentment of the permanent staff.

The patients were evidently not happy in the work, for Dr. Kissen reports many petty squabbles; and only 1 patient is still on the staff after some ten months' service. They were advised to stay a year, to enable the medical staff to assess their condition and working capacity, but 6 resigned after less than three months, 3 after less than four months, and 1 after five months. On the whole their physical health had improved, Dr. Kissen considers, despite a slight loss of weight after taking up work. The scheme was abandoned when the closed ward was reopened, and though there have since been requests by other patients to join the scheme, it can hardly have been said to have proved a success.

One or two reasons for the greater success at Godalming are immediately apparent. Only really fit staff are engaged, and they have to be able to do a full day's work; they are not segregated from the rest of the nurses but share the same mess-rooms and sitting-rooms. Their leisure is more controlled: they may attend dances, but tennis is forbidden, and they must be in by 10.30 P.M. unless they have the medical superintendent's permission to stay out later. Moreover, they are a much-valued section of the staff. It must be recognised, however, that the aim in the two schemes was rather different: Dr. Kissen set out with the deliberate intention of reabling convalescent patients, whereas Dr. Watt employs only patients who are thoroughly fit. Dr. Kissen's experiment has been useful in drawing attention to the special difficulties encountered when a reablement scheme is attempted in a sanatorium mainly staffed by full-time healthy nurses.

CASTRATION AND ŒSTROGEN IN PROSTATIC CANCER

NO-ONE now doubts that in prostatic cancer temporary relief can be obtained from either castration or the administration of œstrogen. Yet the rationale of these procedures remains in part unknown. Either of them, though in different ways, will check the supply of androgen on which the development, maintenance, and activity of the normal prostate depend: œstrogens will reduce the supply of pituitary gonadotrophin and so inhibit the capacity of the testicles to supply androgen, whereas castration will cut off the supply of androgen directly. And any condition in which the concentration of androgen in the blood is greatly diminished will be accompanied by ischæmia and atrophy of the prostate gland and other accessory male genital organs. It seems reasonable to assume that the consequent shrinkage of these organs would at once lower the tension in the affected parts and so alleviate pain, and that the local ischæmia would retard the growth of a tumour. An inquiring man, however, will wonder whether such a simple explanation covers the whole problem. He may ask if a malignant growth in the prostate is ever, apart from the blood-supply, to some degree dependent on androgen for its vigour. Cancer cells are usually regarded as uncontrolled by the tissues of the host; but this may not be a universal rule. Malignancy varies in degree, and it is conceivable that some cancer cells are not so entirely undifferentiated as to be irresponsive to the normal hormones.

Some clinicians regard the giving of œstrogen to patients with prostatic cancer as a more potent remedy than castration, though castration is the readier way to stop the main supply of androgen. If this view is correct, œstrogen must exert some beneficial effect which removal of the testicles does not afford. Possibly œstrogen curtails the output of androgen by the adrenals as well as by the testicles, whereas castration would not have this effect. Meanwhile it has to be remembered that no general anticarcinogenic property has been demonstrated in œstrogen, the reactions to which are mainly confined to those tissues which it regulates in health—namely, the organs concerned with reproduction. Elsewhere in this issue Dr. Ludford and Dr. Dmochowski report that stilbœstrol had no specific inhibitory effect on growth of the mouse tumours used in their experiments.

Œstrogens, however, possess the capacity of increasing the connective-tissue stroma, with an excessive deposition of collagen, in many organs of the body, including the prostate. This reaction has been recorded by numerous observers and has been discussed with abundant histological detail by Mosinger[1] in a comprehensive monograph based on the results of giving large doses of œstrogen weekly to guineapigs. The practical importance of this reaction needs further experiment in connexion with the treatment of cancer; for it has been thought on reasonable grounds that the speed of neoplasia may occasionally be restricted by the local d fibrous tissue—in fact, deposits of collagen to represent a definite, if ineffectual, curative Until this point has been quite elucidated, t siderations suggest that a combination of castrat the administration of œstrogen may be more b prostatic cancer than either remedy used alone.

MALARIA IN NORTHERN CLIMES

THE spread of malaria as an endemic disease is by temperature, the northern limit for benign te for quartan malaria in Europe being the summer of 60°F, and that for malignant tertian 70°F.[1] ture also governs the development of the sexual the plasmodium in the mosquito. This developm 10–14 days at a temperature of 77°F and 14–18 a somewhat lower temperature, and does not t at all if the temperature is permanently below Moreover, in temperate climates malaria tends peaks in spring and autumn. Swellengrebel Buck[3] showed that, in the Netherlands, the peak was due to infection which had been previous autumn and had remained latent winter. An even longer incubation has been proved by Hornberg's account[2] of the out tertian malaria in Finland, which lies north summer isotherm of 60°F—i.e., beyond the bo endemic malaria.

Finland had been almost entirely free from about twenty years when the infection was there during the late war by Finns who had been the Russians. By the end of the summer of isolated cases had been reported; there were in 1942, 262 in 1943, and 892 in 1944. These were all in soldiers. The civilian cases numbered 1941, 75 in 1942, 53 in 1943, and 17 in 1944; of these patients were probably demobilised After general demobilisation in 1945, however, was a great spread of malaria among civilians, the for 1945 being estimated as 1252 cases, excludin Hornberg investigated 856 of these cases. In spi the high susceptibility of children to malaria were no cases in children under 15 years of age, there were not many in youngsters of 15–20. seasonal incidence is illuminating. Between Febr and April, 1945, the mosquito-free period, there 142 cases, and the peak of incidence was in May cases) and June (352 cases), whereas in July and Au while mosquitoes were most abundant, the numb cases fell off rapidly. Hornberg says:

> "As 24–36 days must be assigned in Finland to development of a complete picture of disease in t mission of infection from man to man via the mos half the number of cases would have been infected al before the middle of April—i.e., before there were mosquitoes at all—providing the infection had occ in that year."

The seasonal incidence and the great preponderanc military cases show that most of the patients must been infected the previous year while in military ser elsewhere. Further, the geographical incidence in m cases was too disconnected for infection to have ar where the malaria developed; and in some districts summer temperature was too low to permit infec by mosquito bites that year. The view that infec came from hibernating mosquitoes is put out of c by the appearance of malaria in districts which been free the year before. A questionary sent to patients showed that all but 13 of the 596 who rep had been in military service the previous year in relian Isthmus, where there had then been much laria.

[3] Swellengrebel, N. H., De Buck, A. Malaria in the Net London, 1938; see also *Lancet*, 1938, ii, 891.

The possibility of an epidemic of benign tertian laria in England owing to the return of soldiers ated with mepacrine has already been discussed these columns.[4] In the Finnish cases the incubation-riod must have been 6–14 months, unless the cases re relapses. A long winter incubation in man is not ely to arise in cases of malaria developing in England, ere the temperature lies well within the thermal undaries of endemic malaria.

CARE OF THE AGED IN DENMARK

DENMARK was the first country to introduce the nciple of free provision for the old. In his address the International Conference of Physicians on Sept. 9 Johs. Frandsen noted that the Danish Old Age lief Act of 1891 differentiated clearly between support old age and help to the poor, though the extent of ef to the old was left to the discretion of local horities. In 1922, however, the last flavour of poor- was removed from the Act, and "old-age relief" ame the old-age pension. It is paid to men over and women over 60 whose income is below a prescribed el, provided they have a clean police record for the vious five years and have not lived lives offensive public morals; presumably those who fail in these pects are relieved in other ways. The amount of pension is a basic sum calculated on the cost of ing in the capital, the provincial towns, and the ntry districts. Thus a married couple receive about 5 a year in Copenhagen, £98 in provincial towns, and in country areas; this amounts to about 46% of average net income of an unskilled worker. The m varies with the cost of living, and there are various pplements—for example, a children's allowance for ose who are responsible for children under the age of , fuel and clothing supplements, and a personal pplement for those with special difficulties. Of enmark's 4 million inhabitants some 200,000 are at resent drawing the pension.

As in England, there are both voluntary and municipal omes for the old. The council homes are exclusively r pensioners, the pensions being paid to the homes ith the proviso that the old people are to live under nditions as good as they could buy with their pensions sewhere. Entrance to the homes is voluntary, and e old people usually take their own furniture in with hem; they can prepare meals in a common kitchen, nd suitable interests and occupations are provided. ost of the voluntary homes were founded before gislation for the old was introduced.

Though small properly equipped flats are the most itable homes for old people living alone, they are pensive to provide, and the Danish housing problem as acute as our own. There are, however, some locks of flats for old people, built by the local authorities efore the war. A woman inspector lives in each block help and look after the old people, and in many of he blocks there are assembly rooms for concerts and elebrations. In 1942 there was accommodation, in oluntary and municipal homes and in flats, for some 5,000 old-age pensioners throughout the country. In openhagen most of them are housed in flats; but it is stimated that 285 "places" per 1000 pensioners are eeded in Copenhagen; while in other towns the figure put at 250, and in rural areas at 200 per 1000.

Most of the homes have a sick-bay, and the largest f them has a hospital with a full-time medical officer. n other homes the old people can choose their own loctor, but if they have no preference they are attended y one appointed by the local authority.

"THEY ORDER THIS MATTER BETTER IN FRANCE"

THE tendency in France to elevate therapeutics into an art in its own right has led at times to a finical refinement ill suited to crowded evening surgeries. Perhaps we in this country have erred in a contrary sense in guiding our treatment by its apparent effect on the patient, without much theoretical consideration of the modus operandi of the remedy. In the case of penicillin the charge of pragmatism will not lie against us; but it is interesting to note the methods of our French colleagues in handling a drug of which our experience is somewhat longer than theirs.

A paper by Mollaret[1] on guiding principles in the use of antibiotics makes three major suggestions. The first is that, so far from decreasing as treatment proceeds, the dose should be maintained at its original high level; by this means he hopes to discourage the organism from becoming penicillin-resistant. (We doubt if, in this country, penicillin dosage is often arranged on a decreasing scale, since it is recognised by most users that a drug so rapidly excreted can be kept at optimum levels only by continuous or repeated dosage—in contrast to sulphonamide therapy, for example, where a large initial dose allows a high concentration to be built up which may be maintained by subsequent smaller doses.) His second suggestion is that the final dose should be double that administered previously, so that it shall give the coup-de-grâce to any organism that still resists. Since the concentration in the tissues is usually in excess of that required to deal with the organisms, the advantage of this procedure is questionable; but certainly nothing is lost by it beyond a few hundred thousand units of penicillin. Thirdly, and most ingeniously, he suggests that by giving penicillinase after the last dose of penicillin it may be possible to avoid creating a residue of drug-fast organisms at the end of treatment. This, however, seems to be a case of pursuing logic altogether too far. That strains of organisms exposed in vitro for many generations to sublethal concentrations of penicillin may become resistant to penicillin nobody doubts; but that this resistance will develop in the few hours while the last remnants of a therapeutic dose are being excreted from the body seems most unlikely. In fact resistance to penicillin seems to develop only rarely under therapeutic conditions, and may best be avoided by attention to Mollaret's first suggestion.

Though the last words on the administration of penicillin have yet to be said, we do not yet see reason to echo here the dictum of the Rev. L. Sterne.

DEATH ON THE ROAD

METHODS of reducing road accidents still need much study. Mr. J. S. Dean, in a recent book,[2] makes some interesting and meritorious suggestions for reducing these accidents. The installation of governors on vehicles subjected to a general speed-limit would doubtless be beneficial, though the manufacture of any mechanical device presents difficulties at the present moment. Footpaths beside all roads are also desirable, but the arrears of road maintenance which piled up during the war years will use up most of the money available for the improvement of highways for a considerable time to come. Mr. Dean notes that in 1937 private cars were involved in 33·2% of the total road accidents, public conveyances in 6·8%, and commercial vehicles in 14·3%; and he concludes that private cars have the worst accident record. This hardly tallies, however, with the car-mileages he gives for these different types of vehicles, which have the ratios of 14·40 : 3·04 : 7·18. Private cars seem in fact to have just about their share of road accidents having regard to the car-miles driven. There are, of course, more of them than of other types of vehicle on the road.

---

[4] *Lancet*, 1945, ii, 49.

[1] Mollaret, P. *Bull. Soc. méd. Hôp. Paris*, 1947, 63, 643.

[2] Murder Most Foul. A study of the road deaths problem. London: Published for the Public Affairs News Service by George Allen & Unwin. 1947. Pp. 114. 3s. 6d.

Mr. Dean is an advocate of prosecution rather than persuasion of the offender, and there can be little doubt that the enforcement of discipline among all users of the road would reduce road accidents. It is understandable that the motoring associations and the motor industry, which depend for their existence on the good will of the motorist, should advocate persuasion rather than legislation ; but it is perhaps less easy to understand why the Royal Society for the Prevention of Accidents should support a similar policy. When, however, he advocates immediate institution of strong disciplinary measures against the erring driver, yet not against pedestrians who are at fault, Mr. Dean's attitude can hardly be called unbiased ; the fact that he is the chairman of the committee of the Pedestrians' Association may have influenced him to some extent. It is noteworthy that the Committee on Road Safety appointed by the Ministry of Transport in 1943 recommend in their final report[3] that the pedestrian should be treated as traffic, and therefore liable to prosecution on failure to obey traffic-signals—an amendment to the existing law which is long overdue.

In discussing the report at the annual conference of the Royal Society for the Prevention of Accidents, Mr. G. R. Strauss, recently parliamentary secretary to the Ministry, pointed out that there was a drop in the number of accidents in the second quarter of 1947 compared with the same quarter of 1939—a drop from 1560 killed and 58,722 injured in 1939 to 1174 killed and 43,154 injured in 1947. The number of vehicles licensed in the 1947 period was slightly higher. Commenting on this, the Pedestrians' Association[4] note that the improvement chiefly relates to adult users of the road. Child-pedestrian deaths fell less than 5% between 1937 and 1946, while adult deaths fell by nearly a quarter. There has been some improvement among school-children, who can be taught road drill, but 347 children under the age of five were killed in 1946, compared with 329 in 1937 ; and three has now become the most dangerous age for children instead of five or seven.

POTATOES

During the war the housewife's main preoccupation in the kitchen was with masking the monotony of the food she laid before her family. In the last two years her problem has changed : the release of shipping and the resumption of trade with other countries has brought back fish, fruit, and other foodstuffs which had not been seen for six or seven years ; but at the same time, mainly through the rationing first of bread and now of potatoes, the diet has tended to shrink in quantity. The housewife's concern is not so much that her dishes will not be palatable as that they may prove insufficient.

The Minister of Food, faced with the worst potato crop since 1931, has explained that with free purchase potatoes would disappear from the shops next spring. Accordingly he is restricting the normal consumer to 3 lb. a week and the expectant mother to $4^{1}/_{2}$ lb. a week. To offset this he is allowing one extra bread unit a week to children aged between five and eighteen years, and it is possible that for some of these the net result will actually be a gain in calories. For example, in one boarding-school, where the average age of boys is fourteen years, the 3-lb. ration will mean a reduction of only about $1^{1}/_{3}$ lb. (about 527 calories) on the former free consumption of $4^{1}/_{3}$ lb. Used for flour (5·3 oz.) the B.U. is capable of yielding 554 calories, and used for bread (7 oz.) it will yield 454 calories. For many adults however, and notably for heavy workers, the pensated restriction means a loss of both calories bulk ; and for all it means a loss of vitamin C, of potatoes are a principal source.

Those who have the money can turn to other tables, and will thus be sure of getting enough vitamin Those who are poorer may be less fortunate. The of those other vegetables, except that of carrots cooked beetroot, is uncontrolled ; and the cost, h high; may be expected now to rise still further, implies rationing by the purse. Apart from the bility of more controls, a question that needs im attention is whether the time has now come for general issue of ascorbic-acid tablets, as was p the Forces during the war.

A HAPPY BIRTHDAY

Some fifty of his grateful colleagues entertained R Arthur Young to dinner on his birthday on Nov. 6. C. E. Lakin, who presided, described Sir Robert one of the greatest of living physicians, "but best of a great friend." His teaching career at Middlesex H pital began as demonstrator in physiology and contin as pathologist. Finally, in the late war, he had retu to astonish students by showing them how the inte of the chest could be displayed by what they regar as the old-fashioned methods of inspection, palpati percussion, and auscultation. In his years at Middle and at the Brompton he had trained many great physici and even surgeons ; and all whom he had taught wa to express their thanks and good wishes. Mr. Vi Bonney spoke of early days in which Young, alread godsend to students, inculcated the method of learn —applying that logical sequence of ideas which more serviceable than the parrot memory. Thro all the following years he had gone from strength strength, earning the respect of everyone that had to d with him. If honours came late, this did not matt "because in the hearts of all of us he has been top do In his reply Sir Robert admitted to difficulties during time as warden of the medical college : indeed they h led him to join the Eccentrics Club so that a part of existence might be on normal lines. (Perhaps this w also the reason for his association with The Lancet, our principal medical adviser for many years, beginni as he said, when he "used to vet papers of doubt medical veracity, and correct proofs," under the edit ship of Thomas Wakley, jun.) At Middlesex, since the d 58 years and 1 month ago when he entered the sch (younger than is now allowed), he had seen such men Lowne, Powell, Kingston Fowler, Cayley, Couplan Pringle, Bland-Sutton, and Andrew Clark ; and as student in Vienna he had met Ghon. He had started h professional career with two ideas—to be on the staff the Brompton and on the staff of Middlesex—and was deeply thrilled, touched, and gratified to be ent tained on this occasion by a company containing many representatives of these two hospitals, which held in equal affection.

THE CHRISTMAS GIFTS

Though many generous contributions have be received, the Royal Medical Benevolent Fund is st far short of the sum needed to ensure that all its regul beneficiaries are remembered this Christmas. Sir Alfr Webb-Johnson, as president, appeals for further don tions to be sent as soon as possible to the R.M.B. (Christmas Gifts), 1, Balliol House, Manor Field London, S.W.15.

Mr. W. Rowley Bristow, consulting orthopæd surgeon to St. Thomas's Hospital and honorary co sulting orthopædic surgeon to the Army, died in Londo on Nov. 10 at the age of 64.

LOYMENT OF TUBERCULOUS STAFF IN A SANATORIUM*

JAMES WATT
M.D. Aberd., D.P.H.
ICAL SUPERINTENDENT

MILLICENT SHEEHAN
S.R.N.
MATRON

ING GEORGE V SANATORIUM, GODALMING, SURREY

SCHEME was started at the King George V Sana- m in 1928 to employ as nurses and domestics culous women who had satisfactorily completed orium treatment elsewhere and needed a period of ilitation in healthy employment under skilled al supervision. Difficulties experienced in engaging eeping tuberculous domestics led after four years e scheme's being limited to nurses. During the uberculous medical and male domestic staff were ngaged.

was primarily a welfare scheme for the transition sanatorium treatment to normal employment, the d when relapse is most likely to occur. This period habilitation was normally limited to six months to it as many women as possible. Three women to be engaged for every two posts and, in compensa- o their employers, their pay for the first 3–6 months half the normal rate for the post but with full uments. As competition developed with other ona for these women, and as the shortage of its to the nursing profession increased, the scheme ged; after 1937 full pay was given from the time ining, and the idea of three women for two jobs dropped. Still later, as a result of the work of the cliffe Committee, these women were granted very the same rights to pay during sickness and ssion to the superannuation scheme as healthy bers of staff, though still classed as temporary Admission to the superannuation scheme imposes extra liability on employers, because in case of kdown in health pension cannot be claimed for less ten years' service, by which time the risk of relapse mes very small.

STANDARD OF HEALTH

e standard of medical fitness required of candidates high. Their lung disease had to be quiescent and rcle bacilli absent for several months from any um they might still have. If tubercle bacilli peared in their sputum, they were (except 5 persons hom tubercle bacilli were found once without other ence of activity) sent back to a sanatorium for further tment and written off the books. This policy was ned necessary for the protection of healthy members he staff, who were aware of it and reassured by it. healthy and the tuberculous members of staff shared same messrooms and sitting-rooms. We have had evidence of the transmission of infection by this ciation, and it has only been on two or three occasions t healthy staff or their parents have shown any dread nfection.

andidates had to be fit for a full day's work. Part- e workers require much more bed-room and other ommodation and supervision by senior staff than are c available. Though these standards of fitness were uired in most of the cases, a few women who, though had no tubercle bacilli in their sputum, did not form to them were accepted either on compassionate unds or because they had broken down in other hos- als of the same local authority. A risk to be guarded inst is that the sanatorium may be regarded as a mping ground for "crocks" from other hospitals. r that reason the sanatorium officers must have the right to accept or reject sub-standard candidates. As the years have passed, an increasing proportion of those joining under the scheme are trained or partly trained nurses who have broken down with tuberculosis in general hospitals to which it is inadvisable they should return. It is further very important that candidates should be seen personally before acceptance, both by the medical superintendent in regard to medical condition and by the matron for suitability on other grounds. Without this there are sure to be disappointments either for the candidate or for her employers.

CONDITIONS OF WORK

The care of the tuberculous staff here is the responsibility of the medical superintendent, who examines them every month with the matron present. A few who are very fit are examined only every second or third month. They are weighed monthly and have chest radiograms taken every 3–6 months according to the stability of their chest lesions. Sputum, if they should have any, is examined every month or immediately they report having sputum. Radioscopy of artificial-pneumothorax (A.P.) cases is done both by the experienced medical officer giving the refills and monthly by the medical superintendent. Except in the case of the very fat, the tuberculous staff receive each a total of $8^1/_2$ pints of milk a week. They are not allowed to play tennis, but may take part in dances and may stay out after 10.30 P.M. only with the permission of the medical superintendent.

The precautions taken to guard healthy staff from both their tuberculous colleagues and the patients include the wearing of overalls and masks in the handling of soiled linen but not at other times, such as during bed-making; insistence on careful washing of hands before going to meals; on gentleness in stripping beds and moving pillows; on no meals being taken in the wards; on routine disinfection by boiling of all crockery and cutlery used both by patients and staff; and on the usual damp dusting and sweeping. Special emphasis is laid on the risks of borrowing patients' books, accepting sweets or fruit from patients, moistening finger or pencil in the mouth, and allowing patients to talk over a nurse seated at a lower level. They are drilled in careful handling of sputum mugs and flasks, handkerchiefs and pockets, and infected dressings.

The tuberculous staff, having been drilled in all precautions during their own treatment, appreciate all the special points better than do the healthy staff. Their service therefore is in general more intelligent and more sympathetic, and they have a wider understanding of the psychology of the tuberculous patient. The type of nurse who appears to contract tuberculosis is so often the highly conscientious nurse who never spares herself in the interests of her patients.

Here perhaps it is appropriate to pay tribute to the work performed by these staff. We are fully aware of the debt of gratitude that we—and perhaps to a far greater extent the patients of this sanatorium—owe to them. We can with sincerity say we have never had to spur them on to play their part but rather to curb their energies. They have been of all grades up to the rank of assistant matron. All took their share of fire-watching and other activities special to war-time. Many of the student nurses have gone forward for general training with great success and early promotion. Quite a few have served with distinction and maintenance of health in the Services at home and abroad. Many of the post-graduate nurses have reached high rank in the nursing profession—three during the past two years having been appointed matrons of large hospitals.

Apart from any systematic scheme of employment, tuberculous persons tend to drift into sanatorium jobs, sometimes without disclosing a past history of

---

Paper read to the Tuberculosis Association, April 19, 1947.

treatment, sometimes in ignorance that they have had any chest disease. During the 25 years since the sanatorium was opened, about 2200 persons have been taken on the staff. Of these, 4 were discovered who had concealed a previous history of tuberculosis, and 14 were discovered, mostly by radiography on joining, with preexisting tuberculosis of which they had been ignorant. Of these 18 so screened out, 9 were sent away for sanatorium or hospital treatment and 2 for observation without treatment. Others with previous tuberculosis may have been missed, especially before 1929, the year when it became the rule for all staff joining to have their chests radiographed.

RESULTS

Since 1928, when the policy was adopted of employing tuberculous staff, 203 more have been engaged up to March 8, 1947, and the fate of these persons is the main subject of this report. They are dealt with separately, as they were deliberately accepted as suitable cases for employment, though sometimes, as already indicated, under pressure of compassion or expediency.

Their average duration of service was 20·3 months, which gives an aggregate of 343 person-years. Their average age on joining was 25·5 years, and 28 of them were under 21 years of age. Their rank was as follows:

Student nurses	62
Staff nurses	51
Assistant nurses	36
Sisters	15
Domestic assistants	12
Porters..	12
Medical officers	10
Others	5

They were classified medically as follows:

Respiratory tuberculosis:

A	77, of which 8 were pleural only
B1	29
B2	88
Not classified ..	5

Other forms of tuberculosis:

Peritonitis	1
Chondritis	1
Adenitis	2

The medical quality of the material dealt with may also be judged from the forms of treatment they had had:

Artificial pneumothorax ..	84 cases, of which 9 had been terminated before they joined (2 were bilateral)
Phrenic evulsion	18
,, crush	9
Thoracoplasty	5
Extrapleural A.P.	3
Oleothorax	4
Plombage	1

Weight:

83 gained an average of 6 lb.
86 lost an average of $6^1/_4$ lb.
34 no change or not recorded.

Condition on leaving:

Quiescent	157
Much improved	2
Improved	2
Stationary	12
Worse	30

Fitness for work on leaving:

Full work	156
Light work	7
Unfit	40

Relapses.—Of the 203 persons 8 had minor chiefly pleural effusion in A.P. cases, ending in and resumption of work. In 30 there were major rel which led to their discharge from the service; 28 of were returned to sanatoria or hospital for further ment. Tubercle bacilli returned to the sputum in these cases.

Exactly half of the relapses occurred in the 12 1928–39, and the other half in the $7^1/_4$ war and p years from 1940 to March, 1947. The number at during the first period was 94, and during the the shorter, period was 109. The strain on all staff, even apart from conditions directly caused by war, has been greater during the second period to increasing shortage of staff, rationing of food, the more intensive character of treatment patients.

Deaths.—No complete follow-up has been but of the 203 persons 10 are believed to have tuberculosis, 1 of abdominal cancer, and 1 of pancreatitis. Of the group of 18, 2 are known to dead.

CONCLUSIONS

Taking into account the medical quality of the dealt with and what might be called the normal expe tion of relapse, especially during the first year completing sanatorium treatment, we judge that relapses among 203 tuberculous persons in an ave period of observation of over 20 months is consider less than would have occurred had these ex-pati gone to their homes or their ordinary employm We have no means of testing this by a control, tuberculosis officers working in a busy dispensary in a better position to pass judgment. Alternati other sanatoria with similar employment sche may be able to test their results against those descri today.

NEW CASES OF TUBERCULOSIS AMONG STAFF

A matter of very great importance but not stri relevant to the main part of this investigation is question of the incidence of tuberculosis among sa torium staff hitherto free from that disease. Since sanatorium opened in June, 1922, records have b kept of all sickness among staff; and, though it did become routine procedure to radiograph the ch of all joining till 1929, we think it unlikely that cases were missed while they remained here. Exclu medical, clerical, and male domestic staffs, none of wh developed tuberculosis, and for whom exact figures not at present available, 2009 persons joined the staying various periods. This number includes student nurses seconded here for an average period three months. The total period of exposure to was 2118 person-years or the equivalent of about persons on the average at any one time. In this pe of nearly 25 years, 14 members of staff have develo tuberculosis:

4 had a primary infection, all with a good prognosis.
4 had erythema nodosum alone.
3 had a pleurisy alone.
3 had frank pulmonary tuberculosis.

These 14 cases represent an incidence of less than 0· per annum of those at risk. If we remember that great majority of staff joining belong to the age-gro in which tuberculosis has the highest incidence, we cl that this result is extremely satisfactory; and, if ot sanatoria up and down the country can publ equally good figures, the fear of sanatorium nurs which is so often expressed should be complet dispelled.

NATIONAL INSURANCE AND THE SELF-EMPLOYED

MINISTER'S SPEECH

OCTORS will be interested in last week's speech by JAMES GRIFFITHS, Minister of National Insurance, hich he explained the self-employed man's rights responsibilities under the new National Insurance me. The scheme, which is to come into force next , is, he said, to be universal; but the conditions been varied to suit the different ways of life. There be three classes: class 1 comprises those employed r a contract of service, no matter how high their ies; class 2, those gainfully occupied on their account, including those who, while not employed r a contract of service, are employed under a contract ervices; and class 3, those who are not gainfully pied. For the three classes there are different ributions and benefits.

OBLIGATIONS UNDER THE ACT

lf-employed people who are not already insured under r the health, pensions, or unemployment schemes have to register early next year. They will complete m of application which will be available at post es, employment exchanges, and local offices of the stry of National Insurance. They will receive a ribution card which, when the scheme starts in , they will have to stamp each week. The weekly 2 contributions are 6s. 2*d*. for a man and 5s. 1*d*. a woman; but the Minister has powers to exempt payment those whose income does not exceed a year.

BENEFITS

return for his contributions the self-employed man sickness benefit, maternity benefit for his wife, fit for his widow if he dies, guardian's allowance his children if both parents die, retirement pension his old age, and death grant to help with funeral enses.

kness Benefit.—The Act provides that the self-employed shall get this benefit on the same terms as an employee. weekly rate is 26*s*. for himself, 16*s*. for his wife, and *d*. for his first child. A single woman gets 26*s*. a week, for a married woman who is herself insured the rate is

If the insured person has contributed for three years more the benefit continues, however long the illness, replaced by retirement pension; if contributions have paid for only six months the benefit lasts for a year.

aternity Benefit.—This is of two kinds: a lump sum and a weekly payment of £1 for four weeks. A woman is in gainful employment will be entitled to a special wance of 36*s*. a week for thirteen weeks.

etirement Pensions.—Pension age in the scheme is 65 a man and 60 for a woman; and the basic rate is 26*s*. ek for men and 16*s*. for women. The pension will not be at 65 to a man who continues at his ordinary work; when eventually he retires he will receive pension for self and his wife. Special provision has been made for es who are doing paid work outside their own home es. There is no means test; but if a man, after retiring, es up other work his retirement pension will be reduced 1*s*. for every 1*s*. he earns over 20*s*. a week.

f, on reaching pension age, a man carries on with his inary work, his pension when he does retire will be at a her rate: the amount is to be increased by 1*s*. a week every twenty-five contributions paid after pension age. wife's pension, paid on his insurance, is increased in same way for every twenty-five contributions he makes ile both are over pension age. If he is still in business at 70, n the retirement pension, with the increase, is paid without restriction. After age 70 for men and 65 for women re are no retirement conditions for payment of pension, there is no reduction on account of earnings.

he husband's pension insurance provides a pension for wife as well as for himself; the basic rate for her is 16*s*. ile she is under 60 this 16*s*. is paid as part of the husband's sion. After she reaches the age of 60 the pension is paid ependently to her, unless she is gainfully occupied and has retired from her regular employment.

If a man is over 65 or a woman over 60 years of age at the beginning of the scheme, he or she will not be in the scheme at all. A man over 55 or a woman over 50 will have to contribute for ten years before they are eligible for retirement pension: and if they do not wish to qualify for pension they may, on reaching pension age, decide to receive a refund of the retirement pension part of their contributions. Those who enter the scheme at earlier ages will have no reduction in pension.

Widows.—For each of the first thirteen weeks of widowhood 36*s*. is to be paid. Further pension depends on circumstances. With a child under school-leaving age, a widow will receive an allowance amounting to 33*s*. 6*d*. a week; but this sum is reduced by 1*s*. for every 1*s*. by which earnings exceed 30*s*. If she is not entitled to this benefit but is over 50 years of age when widowed and has been married at least ten years, she will get a pension of 26*s*. a week, similarly reduced if she is earning. At 60 these benefits are replaced by retirement pension. New entrants must contribute for three years before their widows will be entitled to these benefits.

Guardians' Allowance.—This allowance amounts to 12*s*. a week for each child where both parents have died; it is paid so long as one parent was insured.

Death Grant.—The amount is £20 if the deceased person was over the age of 18, with smaller amounts for younger people. It will not be paid for anyone who dies during the first year of the scheme, or for anyone who was over pension age when the scheme started, or for a child born before the start of the scheme who dies under the age of 10. For men over 55 or women over 50 at the beginning of the scheme the amount will be £10.

Regulations for the operation of the Act, said Mr. Griffiths, are being formulated by his Ministry with the help of the new National Insurance Advisory Committee.

HOSPITAL RECORDS

COURSE AT OXFORD

A COURSE-CONFERENCE * for hospital records officers held at Oxford in September provided, so far as is known, the first opportunity for those in Great Britain interested in hospital medical records to meet and exchange information. The meetings were attended by 100 people.

Miss ELSIE ROYLE, of the Christie Hospital, Manchester, dealing with the duties and responsibilities of records officers, said:

> "The qualifications of a records officer include all the virtues of tact and diplomacy, initiative and energy, good humour and patience, a progressive outlook, and the ability to organise and to teach. To these personal attributes, a knowledge of medical terminology, anatomy, and physiology, and an appreciation of statistical theory should be added, and last—and probably most important—experience in hospital and medical ethics."

Miss Royle's theme was that the medical profession needs trained help in the analysis and presentation of the results of its hospital work, and that if hospitals are to have good medical records and to use them intelligently someone must organise their preparation and analysis. This organisation is a task for which clinicians have insufficient time; and all the work connected with records should be concentrated in the hands of a trained officer.

Mr. H. COTTON, of the Nuffield Bureau of Health and Sickness Records, Oxford, described the purposes and uses of medical records in hospitals. He observed:

> "The main need today is for a broadly uniform system of medical record-keeping in British hospitals. If record-keeping is indeed a scientific task, the laws of the science should be discovered and generally applied. A uniform system would not mean regimentation. It would mean that certain well-defined principles would be followed by all hospitals, with adjustments best suited to individual requirements. It follows that if medical record-keeping

---

* A digest of the proceedings, price 2*s*. 6*d*., may be had from Mr. H. Cotton, 10, Parks Road, Oxford.

is to have a broad plan, and if the best techniques are to be adopted by all concerned, there is a need for persons versed in the plan and skilled in the techniques. This means that the production and care of medical records should not be allotted haphazard to persons with no special aptitude, training, or experience. Trained medical records officers are essential members of modern hospital staffs."

Prof. J. A. **Ryle** indicated how the absence of records, or the inability to use them, can be a very real handicap to a clinician, whether a junior or senior member of the hospital staff, a consultant, or one holding a public appointment. He emphasised the advantage of teamwork, adding that today the almoner and the records officer are just as much a part of the medical team as the pathologist, the physiotherapist, and others. Follow-up, he said, should not be limited to a few special diseases; and any follow-up scheme depends for success on accurate and readily accessible records.

Dr. P. L. **McKinlay**, medical statistician to the Department of Health for Scotland, speaking on records as potential data for statistics, pointed out that hospital records will provide information only on intercurrent morbidity, and even in this respect their capacity must not be over-estimated. For instance, one result of modern drug therapy is that many diseases formerly treated in hospital are now being treated at home; moreover, hospitals select their cases to some extent. The sickness of the community as a whole, therefore, is not reflected in hospital figures. Other elements which have to be studied in assessing public health are predisposing factors, prognosis, and criteria of response to therapy. Hospital records can contribute some information regarding the first and second questions. Prognosis is more easily determined, from the community point of view, from data contributed by general practitioners.

The hospital administrator's view was put by Mr. **Stephen C. Merivale**, house governor of the Bristol Royal Hospital, who said that the position of the records officer is clearly that of a departmental head, responsible to a records committee consisting almost wholly of medical staff for all matters affecting records generally, and to the house governor for administrative matters affecting the hospital as a whole. The records officer should be responsible for the appointments system, the registration of all patients, the journeys of notes throughout the hospital, the allocation of typists and stenographers engaged on typing clinical notes and letters to outside practitioners, and the more generally recognised duties of filing, indexing, and analysing medical records. Where there is a medical library, it should be under the records officer. If the best use is to be made of a hospital's beds, a central waiting-list should be compiled by the records officer, who under the direction of the various clinicians would initiate the admission of patients to hospital.

The subjects dealt with in a syllabus covering eight days included medical nomenclatures and classifications, unit records, diagnostic indices, appointments systems for patients, medical terminology, microfilming, and medical and surgical dictation.

The following expressions of opinion by those attending the course-conference appeared to command general assent:

1. In all hospitals adequate documentation of medical service should be the rule.

2. In the larger hospitals at least, responsibility for the production and care of medical records should be assigned to a person (not necessarily medically qualified) skilled in this work.

3. The person to whom this work is assigned should be designated "medical records officer" and should have the status of a departmental head.

4. The medical records officer should be qualified by training and practical experience for the work undertaken; the subjects studied should include anatomy, physiology, medical terminology, organisation techniques, filing and indexing methods, photographic and microfilming methods, coding and classification, interdepartmental relations, interview technique, simple statistical methods, and, in some cases, punched-card methods.

5. There is a need for training facilities. One meeting this need initially would be by the establ training schools for medical records officers in one hospital and one provincial hospital; the hospitals should be first equipped with a records department of the efficient and up-to-date kind.

6. A basically uniform system of medical record should be devised, not to prescribe pro formas for doctors but to standardise methods of registration techniques for the preparation, storage, and indexing medical records.

REGIONAL OFFICERS

The following is a complete list of the senior trative medical officers who have been appointe the regional hospital boards:

North-east Metropolitan.—Dr. J. I. P. **Wilson**, intendent, Hackney Hospital, and a former E.M.S. hospital officer.

North-west Metropolitan.—Dr. H. M. C. **Macaulay**, for Middlesex.

South-east Metropolitan.—Brigadier H. L. **Glyn Hu** commandant of the R.A.M.C. depot, and inspector of Home Command.

South-west Metropolitan.—Dr. W. J. **Gill**, superinte Paddington Hospital, director, E.M.S.

Birmingham.—Dr. S. J. **Sourlock**, superintendent, Mary's (Roehampton) Hospital, Ministry of Pensions.

East Anglian.—Dr. J. B. **Ewen**, principal assistant m officer, hospitals section, Middlesex County Council.

Leeds.—Dr. A. B. **Williamson**, M.O.H., Portsmouth.

Liverpool.—Dr. T. **Lloyd Hughes**, M.O.H., Middlesbr

Manchester.—Dr. F. N. **Marshall**, a senior medical Ministry of Health.

Newcastle.—Dr. W. G. **Patterson**, M.O.H., Surrey.

Oxford.—Dr. G. C. **Williams**, M.O.H., Oxford.

Sheffield.—Dr. W. A. **Ramsay**, superintendent, Crun Hospital, Manchester.

South-western.—Dr. G. C. **Kelly**, a senior medical of the Ministry of Health.

Wales.—Dr. A. T. **Jones**, medical officer, Welsh Boa Health.

Parliament

QUESTION TIME

Cholera Vaccine for Egypt

Dr. S. **Segal** asked the Secretary of State for Fo Affairs how many thousands of doses of cholera vaccine been sent from this country to Egypt; and how had been distributed.—Mr. E. **Bevin** replied: Quantities represent about 1,400,000 doses. Of this total I am info that 155,000 c.cm. were supplied from stock at the tin the outbreak and were manufactured in or after June, The balance was manufactured in September and Octob this year. As regards distribution, 25,000 c.cm. have supplied by the War Office to the Egyptian Air Fo 220,000 c.cm. to General Headquarters, Middle East, an the British Embassy in Cairo for inoculating members o British Forces and British civilians. The balance of 1,800,000 c.cm. was supplied by British firms to the ord the Egyptian Government. Dr. **Segal**: While I thank Minister for the detailed reply, which I hope will do a g deal to remove some misconception in Egypt, may I a it would not be a humane action on the part of this cou if a team of expert epidemiologists could be sent out to Eg to assist that country in coping with this dreadful plag Mr. **Bevin**: I must say that with all the difficulties going in the world I am extremely short of this type of per but I will look into it.

Three in One

Dr. **Segal** asked the Minister of Defence when he w undertake to institute a unified medical organisation for three defence Services, in order to economise in man-p and medical supplies.—Mr. A. V. **Alexander** replied: I explained on July 9, it has not yet been established the institution of a unified medical service is to be pref e maximum degree of coördination between the existing ices. Dr. **Segal**: Has the mind of the Minister really not able to travel any further distance on this matter since 9? Mr. **Alexander**: I said that the matter was under mination, but if one is talking about either coördination tegration, one must first be satisfied that it is going to ove efficiency or reduce costs.

r **Henry Morris-Jones**: Is not the Minister aware medical officers of both the R.A.F. and the Army writing to the medical journals week by week to say they have virtually nothing to do, and, in those mstances, would he take steps to economise in man-power regard to such men? Mr. **Alexander**: I must say that ve seen one or two comments of that kind, but they do agree with the advice given by their senior professional sers. Dr. **Segal**: Would the Minister take steps to some coördination of the specialist services of the e defence Forces? Mr. **Alexander**: Certainly; that is dy being done.

Specialists in the Services

lonel M. **Stoddart-Scott** asked the Minister of Health hether, in view of H.M. Government's decision to reduce size of the Services, he would reduce the age-limit of ical and graded specialists, who were now liable to be cripted up to the age of 40, in view of the shortage of ialists in civil life, and (2) if, in view of the large reduction e size of the three Services, he would accelerate the release octors and dentists now serving with the Forces; and if would assure the House that there was a proportionate ction in the number of those who were now conscripted iew of the shortage of doctors and dentists in civilian tice.—Mr. **John Edwards** replied: The Minister is ised on the recruitment and release of doctors by the ical Priority Committee under the chairmanship of Haden Guest. I am awaiting their advice on the effect e recently announced reductions in the size of the Forces. regards dentists the position is to be examined by my rtment with representatives of the Services and the dental ession later this week.

Venereal Diseases in the Services

eplying to a question, Mr. E. **Shinwell** gave the following s per 1000 strength for the incidence of venereal disease ong British troops during the first two quarters of 1947:

—	1st quarter	2nd quarter
ted Kingdom	5·2	5·6
many	36·4	34·8
y	23·7	34·1
tria	36·8	34·7
ddle East *	6·7	4·7
East	32·6	27·7
an †	61·2	46·8

s a result of administrative changes. Middle East includes Malta and East Africa as from April 1, 1947. The sharp fall in the 2nd quarter is at least partly attributable to a reduction in the number of troops in Greece, where the rate of venereal disease was high.

e number of troops in Japan is small and sharp fluctuations are therefore to be expected.

Our Calories

Mr. H. R. **Spence** asked the Minister of Food what was the orie intake per head shown by his most recent dietary vey; and what was the figure for the nearest corresponding te last year.—Dr. E. **Summerskill** replied: The most recent vey results are for July, 1947, which show an average ake of 2287 calories for working-class households from d eaten at home. The figure for July, 1946, was 2282 lories.

Replying to a question, Dr. **Summerskill** stated that the timated national average calorie intake from all foods, tioned and unrationed, was 2870 per head per day. Consumption by individuals within this total differed widely. e added that the figures were obtained by dividing the nsumption of the country by the population.

Winter Rations in British Zone

Mr. R. W. **Sorensen** asked the Secretary of State for oreign Affairs what calorie scale was likely to operate in e British zone of Germany during the winter: and whether ere was an increase of available German-grown foodstuff er last year.—Mr. C. P. **Mayhew** replied: It is calculated that the ration in the Combined zone can be maintained throughout the winter at its present level of 1430 calories per day for the normal consumer. Owing to last winter's severe weather followed by the summer drought supplies of German-grown foodstuffs in the Combined zone will be less than last year. Mr. **Sorensen**: Can we take it that the ration of 1400-odd calories will be honoured? Mr. **Mayhew**: Yes. At least I can say that the stock position, so far as bread grains are concerned, is very much better than last year. Mr. R. R. **Stokes**: Will the Minister confirm that there is not the slightest chance of doing this unless the imports of food during the October and November months reach 814,000 tons and during December 700,000, and that there is not the slightest possibility of those figures being achieved? Mr. **Mayhew**: I think that is over-pessimistic, but I would not like to challenge the figures without notice.

Help for the Children

Mr. **Sorensen** asked the Secretary of State for Foreign Affairs what was the position respecting the British contribution to the Children's Emergency Fund of the United Nations; and whether our contribution was financial or in kind.—Mr. **Mayhew**: H.M. Government regret that in present economic conditions they cannot make a contribution to the International Children's Emergency Fund either in money or in kind. It is hoped, however, that the fund will benefit from voluntary contributions raised in this country under the United Nations Appeal for Children which H.M. Government have agreed to facilitate. Mr. **Sorensen**: Is it not correct that a promise was made that contributions would be made to this fund, and in that case, is not the fund likely to be embarrassed if promises are not honoured? Mr. Mayhew: No. I do not think we are going back on former promises. I should emphasise that it is the Government's contribution that is at stake and not the voluntary one. Mr. D. L. **Lipson**: If it is possible for private individuals to send money to this fund, why is it not possible for the British Government to do so? Mr. **Mayhew**: There is a limited supply of goods and services which can be supplied overseas. It is better for this to be covered by voluntary contributions rather than Government contributions.

Accommodation in Mental Hospitals

Mr. **Sorensen** asked the Minister of Health to what extent overcrowding of patients existed in public mental hospitals; what was the present shortage of staff and closing of beds compared with a year ago.—Mr. A. **Bevan** replied: In January patients exceeded the available recognised accommodation by some 16,600 out of 112,000, and 3000 beds were out of use through staff shortage. Comparisons with other years are useless, as accommodation standards were revised in 1946.

Use of Cars by Doctors

Mr. L. **Hutchinson** asked the Minister of Fuel and Power if he would allow medical practitioners, with the limited amount of time at their disposal, and who had to be on call all day and every night, to use their cars for all purposes within a radius of ten miles of their consulting-rooms, in order to permit them some measure of relaxation and yet remain within speedy recall. Mr. H. **Gaitskell**: This matter on which I have received certain representations from the British Medical Association is under consideration.

Deaf-aid Prototypes

Mr. F. J. **Erroll** asked the Lord President of the Council how many prototypes of the two-piece deaf-aid now being manufactured for free supply to the deaf were produced; how many were tried out on deaf persons, and for what periods of time; and if these persons were given an opportunity of comparing the Government deaf-aid with the best types of deaf-aid currently available.—Mr. H. **Morrison** replied: For the final tests, four working models were made of the hearing-aid designed by the electro-acoustics committee of the Medical Research Council. These models were tested at clinics in London and Manchester on 27 persons with various degrees of deafness and well practised in the use of aids. The individual tests of the aid lasted about three hours. Comparison was made in each case with the patient's own previously prescribed aid, and also with a highly recommended American instrument. Twenty of the patients heard best with the new aid, and three others equally well. All the subjects commented on the new aid's exceptionally good reproduction of speech and preferred it on that account.

In England Now

A Running Commentary by Peripatetic Correspondents

"Is this your medical electric brain?" I asked. "Yes," said the Great Inventor, "it is designed to perform systematically and mechanically what doctors have previously managed by a mixture of astuteness and luck—to notice that one thing varies significantly with another. For example, there has probably been a significant relationship between maternal rubella and congenital deafness for centuries, but it was not till the last few years that anyone noticed it.

"On all these cards I have marked (with the punched-hole system) everything that could possibly influence health—sex, age, habits, hobbies, diet, and so forth. The machine goes steadily through the cards, and whenever it finds that one factor is accompanied by another in a significant proportion of cases it rings a bell and displays the two key numbers and the degree to which they are related. I thought I was going to make hundreds of important discoveries and also be able to stop thinking, which I have always found a strain."

"Wasn't it enormously exciting when the first result came through?" I asked. "It was," he agreed. "I shall never forget the thrill when I looked up the two key numbers and learnt that erythroblastosis fœtalis was four hundred times rarer than the average in the offspring of opium-smokers. I was about to ring up all the big maternity hospitals and suggest that they ordered some opium pipes straight away when I remembered that 99% of Chinese are rhesus-positive and that most opium-smokers are Chinese; hence this remarkable relationship. Since then I have been told hundreds of things by the machine, but many are a bit obvious (such as that carcinoma of the prostate is more common in the male), some are already known (like infective endocarditis being related to tooth extraction), and the rest are largely cryptic, like the opium-smoking sample. Most of these puzzles have turned out to be social medicine in disguise. For example, pulmonary tuberculosis is five times commoner in those without telephones merely means that a small income makes you more likely to get tuberculosis and less likely to get a telephone. The last result that came in is that rheumatic fever is three times commoner in those who sucked dummies in babyhood. You might think this revealed an important relationship between chronic rubber poisoning and an allergic response to streptococcal infections, but I'm not caught that way now and I'm pretty certain it's just that both rheumatic infections and dummy-sucking are commoner among the poor.

"Altogether," he ended with a sigh, "the machine has been rather useless so far and I fear I shall have to think after all if I want to discover anything." "On the contrary," I told him, "I consider you should send your results to THE LANCET forthwith. You have shown that if whenever A occurs B almost invariably happens too, this in no way proves that A causes B. If doctors and research-workers all realised this, the amount of nonsense published would be reduced by at least root sigma chi squared, and the paper shortage would be no more."

* * *

Last week, with cholera still in the news, came the coincidence of a gift of a book from my great-aunt whose uncle was a local pharmacist. Her uncle's book had a lock on the covers. I opened it carefully and out fluttered a four-page pamphlet headed: ANTI-CHOLERA TINCTURE: *Prepared only and sold by D. F. Cooke at the Medical Hall, 18, High Street, Whitechapel, London.* A delicately printed text followed:

> "The ingredients of which this medicine is composed having been eminently useful in India, in cases of Asiatic Cholera, a gentleman was induced to recommend it in this country, on the breaking out of that dreadful disease, and was astonished and pleased to witness the numerous instances in which it proved successful."

After a long discourse, including the assertion of never-failing cure in the English cholera and ending on a truly dramatic note that left today's advertisements cold, there came the customary list of testimonials from Merchants, Skippers, Gentlemen, and an
For instance:

> "Dear Sir, You must please let me have three more bottles of your Anti-Cholera Tincture. . . . demand for it this summer . . . has been so great could have sold almost any quantity. . . . A lad of was taken so bad a short time back with an at Cholera that he was drawn double with the gave him a dose of the Tincture, it relieved him and before the time to repeat it he appeared nearly I only had occasion to give him two doses. I am subject to violent attacks of bowel complaint, but dose always sets me to rights. You are quite to make what use you like of this. I remain, yo John Dickinson, Sen. Master of the *Zephyr.* Lincolnshire."

Another, dated Sept. 24, 1846, read:

> "Sir, I am very glad to have this opportunity of my testimony in favour of your Anti-Cholera not to say of its good in every instance of Spasm and Complaints; . . . When I was at St. Petersburg, I could disposed of a large quantity in a few hours, as, the bad state of the water there, the Bowel Complai very bad. . . . I expect to leave Hull shortly for A so you will not omit to send me a good supply. I yours respectfully, Thomas Popplewell."

In the book the pharmacist had written, in hi formed script, many formulæ for Liquid Horse B Cough Balls, Pick-me-up, Curious Essence, and so He had written his own index, so I looked up the C Tincture. Reduced to a four-ounce size it was:

℞

Gum. camphor. ..	..	dr. ii
Ol. menth. pip. ..	..	oz. ss
Tinct. opii ..	..	oz. i
Sp. vini rect. ..	ad	oz. iv

(Put into half-ounce bottles)

Not so mysterious after all! There is no indica dosage, but the text mentions "a few drops" first dose. It was sold in bottles at 1*s.* 1½*d.* and each, duty included.

* * *

Women doctors, it seems, have rarely been encou in this part of Canada before. The resistance uninoculated community is low. One of our first p refused any kind of anæsthetic while Alison put fo stitches in his arm. Astonishment at her seen render him slightly numb. They parted with n congratulations and the end-results were very factory. Things have not always gone so sm in the surgery since then. One day I was interv a patient while Alison scrubbed up. When she en ready for action the much impressed French-Ca seized her hand and kissed it fervently. You co explain that that sort of thing simply holds things u

* * *

Speaking of tattoos, among the seafarers (not, I Merchant Navy personnel) who pass in and out door the most striking example I have seen was ad the epigastrium of a wiry A.B. back from a tr South America. In conversation before my exa tion began, as often happens nowadays, the quest grub cropped up. "It's all right down there," he "Not like this hæmorrhagic country, where a man get a bellyful." I made some non-committal reply asked him to do the usual—down with the trouser up with the shirt. He obliged with alacrity an played, neatly printed across the appropriate spac single word EMPTY.

Then there was the young fireman who was c reluctant to display his chest. After a little persu however, his shirt came off. Written in blue ove nipple was WATER, over the other MILK. I asked wh this was his own idea, or the suggestion of some practitioner of the art. "Neither," he answered, an attempt at a rueful grin, "I got very drunk, an mates had it done." What worried him was not permanent reminder of a fall from grace, but the exp tion he would have to make to his betrothed after fast-approaching wedding.

Letters to the Editor

SOCIAL MEDICINE

Sir,—I have been interested to read the recent corre- ndence, initiated by Dr. Beryl Harding, which has peared in your columns on the subject of social workers. Hospitaller of the Order of St. John of Jerusalem I uld like to draw attention to the work which has been ne, for many years, in this field by members of the John Ambulance Brigade—more particularly by women of the nursing divisions.

In a letter to the *Times* of Oct. 24, Miss M. E. Johnston, retary of the public-health section of the Royal College Nursing, mentions the following fields in which the vice of voluntary workers would be of value : “ Atten- nce upon doctors at immunisation clinics. dentists dental clinics, the weighing of children, and the raction and filing of record cards.” These and many er services have been fulfilled by members of the gade. They have also helped in following up cases, ncipally ex-Service patients for the Ministry of nsions ; and in order to acquaint those concerned with ir readiness to extend this assistance the brigade ued a leaflet to all hospital matrons and almoners, ne two years ago, indicating the types of duties they re willing to undertake.

Furthermore the brigade has a nursing aid service, nned in conjunction with the Queen's Institute of trict Nursing, and available to any district nurse hing to avail herself of it. This provides many oppor- nities of contact with sick members of the community d of putting those in need of treatment, or advice, in ch with the proper authorities.

It is difficult to foresee the exact working of the new lth services ; but, as a voluntary organisation, the gade welcomes any indication from public or profes- nal bodies that their services are acceptable. Under new Act voluntary organisations concerned with bulance services have been asked to act as the agents local authorities, and to assume increased responsi- lities. Official indication that such coöperation will be eptable in other spheres would do much to draw sh recruits to the ranks of the brigade and encourage se who are already endeavouring to live up to the tto of the Order—“ *Pro utilitate hominum.*”

PRESENT STATUS OF DISC SURGERY

Sir,—I should like to comment on your leading article Nov. 1, concerning fusion of the spine after inter- rtebral-disc operations.

Many successful lumbosacral fusions, using a simple bee technique, have been done in the past for low ckache due to lumbosacral arthritis. These patients esent with stiffness of the lower lumbar spine, and diologically show a diminished L5-S1 disc space with arginal sclerosis and often peripheral osteophytes. is condition can now be recognised as an adaptive ange of the joint surfaces in response to the degenera- on and resulting mechanical inadequacy of the inter- ning disc. Nature has, in fact, compensated by the rmation of a fibrous ankylosis which is, in some cases, perfect and painful.

If we now consider bone grafting in general, it must be reed that success is more constantly achieved with the ired than the single bones of the limbs, and this we cribe to the splinting action of the intact partner bone. pplying this idea to extra-articular arthrodesis of the p, we can explain why any variety of graft spanning e joint usually consolidates successfully when applied the fibrous ankylosis of the healed tuberculous hip, d often fails alone with a relatively mobile joint, as in steo-arthritis. The less movement there is before opera- on, the less strain there will be on the graft and thus e greater the chance of successful consolidation.

This conception may explain the varied experiences ith spinal fusion after removal of the intervertebral sc. Abnormal mobility of the lumbosacral junction, s a result of the degeneration of the disc, can usually be emonstrated at these operations. This will allow the great forces present at this level, as Falconer states, to hinder or prevent successful fusion by graft. If this argument is correct no modification of technique would materially improve the results.

It would seem, therefore, that the aim should be to hasten the natural adaptive changes at this joint and remove the whole disc as thoroughly as possible, as advocated by Falconer and Dandy. A fibrous ankylosis between the bodies of the vertebræ will develop, and will in many cases be adequate and painless. Other patients may complain of persistent backache and these will be similar to the type of case described at first in this letter. Here mobility of the junction has markedly decreased as gradual approximation and adaptation of the vertebræ have occurred. Fusion can now be done with the knowledge that the anterior ankylosis, although perhaps incomplete, will mechanically protect the posterior graft from undue strain.

As a parallel example, Guri[1] has stated recently that in tuberculosis of the spine fusion fails to prevent mechanical collapse of the vertebræ. but when this has occurred the healed case with a painful fibrous ankylosis can be grafted quite successfully.

I suggest, therefore, on theoretical grounds that primary posterior fusion of the spine by graft after removal of an intervertebral disc is a potentially unsound mechanical procedure, and that alterations of technique can never endow it with universal success. Efforts at achieving anterior vertebral ankylosis, either fibrous or bony, should receive attention. If this fails, late posterior fusion should be done.

G. V. OSBORNE.

MENTAL HEALTH AND WORLD CITIZENSHIP

Sir,—Some of your readers will be familiar with this title, which is the general theme selected for the International Conference on Mental Hygiene due to assemble in London in August, 1948, as part of a rather larger Congress on Mental Health. This theme has been chosen deliberately in view of the present state of world affairs, in the belief that many of us in medicine—not only in psychiatry—along with our colleagues the psychologists, sociologists, educationalists, and others, have an opportunity of learning to apply some of our understanding of individuals to the problems of group attitudes and international tensions. No doubt psychiatrists should be able to provide the central focus for much of the thinking that is necessary, but they certainly cannot do it alone.

This general theme of Mental Health and World Citizenship has been broken down in a tentative way into various subjects for the different days of the congress: World Citizenship and Good Group Relations ; The Individual and Society ; Family Problems and Psychological Disturbance ; Industrial Relations ; Planning and Training for Mental Health. There are in London discussion groups or preparatory commissions composed of men and women from various allied professions, working each of them on one of these days' topics. In some 14 or 15 other countries there are already groups—in some cases, as in the United States, a great many—working on exactly the same topics. Their material as they produce it will be sent in to the central commissions in London, who hope to put it together and send out a monthly summary of all these various points of view to the other groups throughout the world.

This plan of preparatory action has been made because international conferences are often somewhat sterile, and we hope that in this case we shall be able to get a good deal of the work of the congress accomplished before the meeting next August. At that meeting we actually want to exchange ideas and bring each other up to date in these matters. We hope that out of the work of these various preparatory commissions, which are of course on a national basis, and from the work of a residential International Group which we hope will meet before and after the conference, we shall be able to clarify many of the points of agreement and disagreement. It should be possible to delineate many of the subjects which demand continuing research and inquiry in this medico-sociological field ; and we hope also to be able to arrive at

---

1. Guri, J. P. *J. Bone Jt Surg.* 1947, 29, 136.

some points of agreement, however simple these may be, which could be of assistance to those two important functional organisations of the United Nations, the World Health Organisation and UNESCO, in the tasks to which their constitutions have committed them.

In this country there are a number of groups being planned, but there are not yet so many as there might be. As chairman of the organising committee of the congress, I am writing now in the belief that many of your readers will feel that this provides them with an opportunity for getting together with colleagues from their own and other disciplines to try to study these topics and see what contribution can be made towards the solution of some of these major problems.

Usually when one talks in any gathering about the general purposes of the congress, about our intention to experiment in presenting group opinions rather than individual communications at the meetings, and about our desire to adventure out of our normal field of work into this wider region, one meets with general approval. It is, however, far from easy in these busy days to get men and women to settle down to serious discussion and to formulate their ideas on paper for the benefit of other people: but this is what we want. Certainly in every academic centre in this country there should be sufficient people with concern for the sanity and balance of society to provide separate discussion groups for each of the five topics; and equally, there are many more isolated areas where perhaps the inter-professional nature of the group might be more limited but yet there are people who could get together and produce much that would be of real value.

Careful studies of much more limited subjects coming within the general field of interest of the main topics would also be welcomed. It is hoped that it may be possible to publish, fully or in summarised form in the documents of the congress, such of them as are specially useful.

I hope that this letter may be taken as an invitation of a somewhat urgent kind to those who feel a concern about these matters to do something, and to get in touch with Professor Flugel (the chairman of the programme committee) or with the programme secretary at the office of the International Congress on Mental Health, 19, Manchester Street, London, W.1.

London, W.1. J. R. REES.

TREATMENT OF BOILS

SIR,—With reference to Dr. Foot's letter in your issue of Nov. 1, I should like to suggest that a more reasonable approach to the problem would be on the lines indicated by Hobbs, Carruthers, and Gough in their recent article in THE LANCET (Oct. 18) on the treatment of sycosis barbæ.

It is now established that *Staph. pyogenes* is almost unique amongst pathogenic bacteria in its ability to live on the intact skin, specially in such regions as the anterior nares, eyes, and external auditory meatus. When a boil develops, the surrounding skin becomes infected with cocci, which incidentally are not affected by the use of systemic penicillin. It is natural for the fingers to investigate such a lesion, and they may readily carry the infection to other parts of the body, including the nose, where the cocci may persist for long periods.[1] In cases of recurrent boils some such site for the carriage of infection can almost always be found, and, in so far as I have been able to compare such strains with those from an actual lesion, they have usually appeared to be identical, and therefore equally virulent.

Treatment based on these considerations aims at the elimination of all pathogenic cocci from the surface of the body. With a first boil, the patient should be warned against contaminating his fingers, and the area round the lesion should be treated with penicillin cream and a dry or tulle-gras covering. The use of systemic penicillin will usually obviate the need for any form of wet dressing. If the local treatment is continued for a few days after complete healing, there should be little risk of further trouble unless the nose has been infected. In the chronic case, fresh lesions are treated on the same lines and the site of carriage is found by culture from wet swabs of nose, eyes, &c., which are best taken in the laboratory. Penicillin cream used to disinfect the nose, but if not successful fortnight should be replaced by some mild ointment to avoid the development of resistance cocci.

I have to admit that I have no experience of with manganese. But I should like to point out Dr. Foot makes no mention of the local treatment he is accustomed to use in furunculosis and which have been more effective than he thinks.

London Hospital. F. C. O. VAL

MEDICAL FILMS

SIR,—My committee would like your help in some comments on the recent Ministry of Health *Poliomyelitis 1947*.

First, we welcome the film as being successful aims of conveying information and arousing and so helping doctors to deal with the epidemic as an example of what the Ministry should initiate delay—a series of films, "Recent Advances for Practitioners." Such a series could be compared field of film with your leading articles or annot The great interest shown and the lively throughout the country at showings of *Polion* means that a series like this would evidently great welcome.

Secondly, we note that this film does not be name or names of the medical advisers responsib the information given. It is the policy of this to recommend that all scientific films should bea name of the technical adviser. This principle is ad in the publication of various papers issued by Go ment departments. May we ask you to lend your su to establishing it in the field of medical films?

RENAL CIRCULATION

SIR,—May I be allowed to correct a factual and remove an ambiguity, which is contained in report (Nov. 1) of the meeting of the section of mental medicine of the Royal Society of Medici Oct. 21? Both are contained in the statement attri to me. The correct statement is as follows:

> "There is considerable evidence that the gross h rhages which occur in the portal tracts, and are the lesion in dietetic massive necrosis of the liver, are swelling of the parenchymal cells impeding the lobular circulation and so damming back the blood portal tracts. The same dietetic measures when a to very young rats of 40–50 g. weight, produce no the necrosis in the liver but a hæmorrhagic necrosis cortex of the kidney. This is particularly so if the deficient in choline, and Dr. Baxter, working in Pr Best's laboratory in Toronto, has evidence that the c hæmorrhagic lesions in this condition are a seco phenomenon, secondary to circulatory disturbance quent on the gross swelling of the parenchymal cells. relevance of these observations to the discussion o renal circulation is that in those experiments we h type of cortical necrosis in which the circulatory impa is the result, rather than the cause, of the lesion."

University College Hospital,

H. P. HIMSWOR

DIABETIC NEUROPATHY

SIR,—The annotation on Oct. 25 made no menti Charcot's joints. In the October issue of *Abstra World Medicine* (p. 403) is a report on 2 cases, bo males. The publication of these 2 cases and the ab of all mention of the condition from your more prehensive survey tempts me to report a case now my care in hospital.

My patient is an unmarried woman, a school teacher has been a mild diabetic for many years. Until she c hospital for the investigation of diarrhœa no neuro symptoms had been noticed. Some minor mental sym have appeared since she has been in hospital, with fe suggestive of myxœdema; but these have not respond thyroid therapy. The swelling and joint destructi ircot's disease appeared very insidiously in a leg already dlen as a result of venous thrombosis. There was very ht pain or vague aching in the left knee, but destruction hin the joint progressed rapidly until in a few weeks the e was completely disorganised. The nature of the lesion s confirmed by X-ray examination. When looked for, er evidences of neuritis were found: muscle tenderness, of tendon reflexes, and loss of vibration sense. Loss of aneous sensibility is not pronounced, and the limbs are of trophic ulceration. The Wassermann reaction is ative, and there are no signs of tabes, general paralysis, syringomyelia. Balancing of the diabetic condition and ministration of vitamin B_1 have done nothing to arrest the id advance of joint destruction.

---

[1] Miles, A. A., Williams, R. E. O., Clayton-Cooper, B. *J. Path. Bact.* 1944, 56, 513.

have not succeeded in finding other reports of cases this. I have not previously seen Charcot's disease h diabetes and would be interested to know if the ociation is as uncommon as I believe it to be.

ymouth. T. H. G. SHORE.

MASS RADIOGRAPHY IN FACTORIES

IR,—May I correct a false impression which may e been caused by a statement in your report (Nov. 1, 676) of the mass-radiography service started by the d Motor Company? According to the report, this 'said to be the first installed by a factory." This n had a mass-radiography unit installed in its surgery Sept. 12, 1941, and it has been fully functioning ever ce.

J. V. MANNING
kington Brothers Ltd., St. Helens, Lancs. Medical Officer.

AMŒBIASIS IN CEYLON

IR,—In his article (Oct. 25) Dr. Parkinson makes two ements that particularly call for comment.

iscussing the efficacy of sulphonamides in the treatnt of bacillary dysentery he says that "it has become custom in many hospitals overseas to use these gs as a diagnostic test in cases of dysentery. . . ." asten to point out that this practice, which is efensible in the presence of laboratory facilities, was ainly not the custom in R.A.M.C. hospitals in the ldle East, where a great deal of bacillary dysentery s seen and where there was no dearth of amœbic entery. It was early appreciated that not all cases bacillary dysentery responded to sulphonamides; did these refractory cases respond to anti-amœbic atment. They could therefore not be considered issed amœbics."

r. Parkinson has rightly emphasised, as have others ore him, the importance of adequate treatment for te amœbiasis before it has had the chance to become psing; but a false and very dangerous sense of urity will be engendered if the follow-up is too short. his 42 cases, 15 were reviewed after an interval of two four months, with no evidence of relapse on sigmoidopic inspection and examination of three stools. No ntion is made of whether the stools were fluid and ained after purgation. I consider this important many an apparent cure has broken down with a little gation. I wonder what the stools of the 4 cases t had had further diarrhœa would have revealed if mined during the periods of diarrhœa.

r. Parkinson writes that "the results, both immediate l remote, of this treatment have been impressive. . . ." ely the immediate results are no better than those ally obtained with many different schemes of treatnt relying on combinations of emetine, carbarsone, l emetine bismuth iodide without sulphonamide. ere is no evidence that the addition of sulphonamide the standard "combined" forms of treatment for te amœbiasis, as opposed to chronic relapsing œbiasis, offers any immediate advantage. Remote ults are not given by Dr. Parkinson; two to four nths cannot be considered remote in a condition at is well known for its late relapses. My disagreent with Dr. Parkinson is not that he has neglected follow up his cases for a long period—that was probably possible under Service conditions—but that on the sis of a follow-up inadequate both in method and ration he has recommended a line of treatment.

It is my practice to readmit patients for purgation and amination of six fresh liquid stools, and for sigmoidoscopy with scraping of any suspicious areas, at the end of six weeks, three months, six months, and one year. This I believe to be justified by the importance of prompt treatment for relapses; it is equally important for the chance it offers of appraising the form of treatment.

I would like to end with a special plea for protracted and thorough follow-up, without which our knowledge of therapy must remain incomplete.

Chase Farm Hospital,
Enfield, Middx.
G. RIDDELL ROYSTON.

SEPTIC FINGER

SIR,—Your leading article on Oct. 25, and the three papers published in that issue, raise many important points. So often is a new form of treatment (like penicillin) hailed and used as a panacea, that two of your statements should be plastered up all over the land: "Penicillin is not a substitute for properly planned surgery"; and "No kind of chemotherapy can supplant the evacuation of pus."

It is most gratifying to see that surgeons and others dealing with infected fingers are at last beginning to realise the importance of the relief of tension at the outset of treatment. In my opinion, the dangerous increase of tension associated with these infections is probably responsible for more damage than the infection itself. I feel that the statement about pulp infections applies equally well to the whole hand: "Once tension has been relieved by suitable incisions . . . only meddling will prevent healing in a reasonable time." Might I add to this—provided proper attention is paid to ensuring adequate drainage and active movement from the beginning. With regard to the "hockey-stick" skin incision, advocated by Bolton and others, I would question the necessity for dividing all the fibrous septa, and also the need for two lateral incisions for this purpose. I feel that neither practice is necessary as a routine measure, that they might often be dangerous in opening up uninfected tissues, and that they cause unnecessary damage and deformity to the finger. I agree with Cruickshank and Harrison that minimal skin incision alone is necessary, and pus should be sought for and let out by Hilton's method, to avoid damage to deeper structures. With careful supervision of after-treatment it is quite simple and safe to enlarge the drainage opening if it is inadequate or if pocketing occurs. Excision of infected bone before separation of sequestra is dangerous and meddlesome surgery, as also is early excision of sloughing tissue, even under a cloak of penicillin. Neither will be necessary if early incision with relief of tension and adequate aftercare are carried out. When patients are seen late on and some necrosis of soft tissue or bone has already occurred, it is wiser and safer to let the dead tissue separate off before attempting to remove it.

Bolton and his associates inveigh against hot soaking with early movement, and I am amazed to see that your editorial backs them up. I have employed this form of treatment for the past seventeen years, and I have never seen any but a perfect functional result, with rapid healing. Admittedly the skin becomes sodden after some hours' soaking, but this does no harm whatsoever and is never a reason for stopping. The benefits that accrue in the shape of an improved blood-supply and the relief of pain, allowing of a great increase in active movement, greatly facilitate the escape of pus, promote rapid healing, and prevent residual stiffness. Secondary infection can be avoided with reasonable precautions.

I would strongly deprecate splinting even for a few days. There is no need for the physiotherapist later on to try to get rid of residual stiffness, since this can be prevented from the start. Short-wave diathermy as a form of heat, applied for ten minutes daily with supervision of movement later on—"once contact has been established"—is a very poor substitute for active movement from the outset. When the patient is told that it all depends on him, it is surprising how hard he will work to get normally mobile fingers or hand. And how much better for his morale than letting him feel it is all being done for him! More self-help means fewer stiff fingers.

Hypertonic dressings are devoid of any virtue or value and should be discarded. They neither increase the blood-supply, promote free drainage, nor facilitate movement. Penicillin, by three-hourly intramuscular injection, may be a useful adjunct to treatment, especially with bone involvement. But it is not a substitute for good surgery, and only too often its use has been the reason for bad surgery, or none at all. As regards tendon-sheath infections, I am most surprised that Cruickshank and Harrison had one stiff finger and another needing amputation, out of 13 cases. I feel that these would probably not have occurred if they had added hot soaking with active movements right from the start to their otherwise admirable régime. Prevention is better and safer than rehabilitation for stiff fingers, and it is quite possible even over 55 years of age. They suggest that the use of penicillin should reduce the incidence of secondary tendon-sheath infections. The adoption of sound surgical principles will achieve this end with much more certainty and will allow the penicillin to penetrate through and around the infected area, by relieving the tension and restoring the circulation. Drainage is not necessary, either by means of 'Vaseline' gauze or rubber drains, if the incision is properly placed and hot soaking with active movement is adopted from the beginning.

Webster explains that some of his patients refused injections of penicillin in beeswax and oil, because of local reactions, but these people recovered as quickly as others who continued with the injections. Surely this seriously detracts from the value of penicillin in beeswax and oil for these infections, as well as emphasising the possible danger of injecting masses of insoluble wax and oil into patients' muscles.

Local injection of penicillin around the incision or into the nail-fold would appear to have nothing at all to commend it. It would not diffuse so widely as penicillin in the blood-stream, provided the circulation of blood and tissue fluids is made possible by the relief of tension. On the contrary, it would tend to cause further increase of tension with great increase of pain (as found by Webster), and the risk of more tissue necrosis. The method advocated by Whitwell (Nov. 1) does not seem to be any better, and it is definitely less certain than the relief of tension together with hot soaking and active movements. In my experience it is never necessary to remove the whole nail, and doing so leaves a raw tender area which is extremely touchy for weeks. It may rarely be necessary to remove part of one side of the nail to improve drainage, and the rest may slough off later on. But by this time the new nail has grown down beneath, for some of the distance at least, and the exposed area beyond is no longer raw and tender.

Undoubtedly many cases will resolve without suppuration if treated early with systemic penicillin, provided there is an adequate circulation in the infected area for the drug to reach it. But in many cases an adequate circulation cannot be maintained without early incision to relieve tension, which is a far safer way of discouraging further spread of infection.

A septic finger with a "slough in the tissues by the time that treatment is started" should surely be labelled "too late" instead of "early." Would it not be possible to catch cases even earlier and avoid necrosis altogether, since it is possible to catch them "so early"?

Mount Vernon Hospital, Northwood. ALAN SHORTER.

A BOOK REVIEW

SIR,—In your footnote to my letter published in your issue of Nov. 8 you say, referring to the influence of maternal rubella in the ætiology of congenital cataract: "This important contemporary discovery is not, however, accorded a place in the sections on Cataract, Diseases of the Lens, or the Development of the Eye," but you mentioned at the beginning of the footnote that I was right in saying that the subject was mentioned on p. 54 of the book in question. The first words on p. 54 are: "Chapter VI. Development of the Eye and its Adnexa." I submit, Sir, that you have followed in the steps of your reviewer in that you have made an untrue statement.

London, W.1. J. H. DOGGART.

*** This error was introduced in compressing our reviewer's rejoinder. Mr. Doggart seems to win on points—if only points of detail.—ED. L.

GAUCHER'S DISEASE WITHOUT SPLENC

SIR,—With reference to the article by Dr. (Oct. 18) and the remarks of Dr. G. A. Matthews (the following brief report may be of interest.

Recently I have performed the post-mortem of an infant, aged 3 months, who suffered from hepatoma. The spleen was normal in size (16·1 g. in It had a peculiar pallid appearance and the capsule slightly roughened. On the section the malpighian not discernible and the pulp had the appearance of a honeycomb. In histological sections the pulp was f be packed with large pale cells, about 25 μ in diameter. nuclei were small, hyperchromatic, and in most cells The cytoplasm was colourless in the hæmatoxylin-eosin except for a very fine network of mainly radially fibrils which consisted of rows of tiny granules. In stains the cells appeared pale blue. The cytoplasm stain in frozen sections with Herxheimer's Sudan IV and it was pale brownish-yellow in the Smith-Dietrich No anisotropic substances were found in these cells examined in polarised light. The chemical analysis lipoids in this spleen is being carried out in association Dr. E. Hickmans. The Klenck-Chargaff method of extraction is being used and all that can be said at the time is that the bulk appeared in the ethereal fr which cerebrosides are expected. Only minimal traces of latter are present in normal spleens.

Although the final diagnosis depends on the identi of the lipoid as kerasin the findings strongly Gaucher's disease without splenomegaly.

Pathology Department,
Children's Hospital, Birmingham. H. S. BAA

THE BARBITURATES

SIR,—Your leading article of Oct. 18 was of value to the vast number of doctors who barbiturates regularly.

A further point that should be stressed is the before prescribing barbiturates in cases of anxiety and other functional disorders, of excluding disease. Sir Adolphe Abrahams et al.[1] recently out in an article on acute porphyria the harm may be done by barbiturates, which, in his case, possibly have led to the death of the patient. barbiturates may mask important symptoms and Perhaps the following case will help to clarify this

A married woman, aged 40, was admitted to a home in 1943, with the diagnosis of anxiety state. 1946 she was discharged, improved but not cured. all the time she was on barbiturates. Even after her she was still taking 'Sodium Amytal' gr. 6 and gr. 10 within 24 hours. Her symptoms were still the —mental instability, lack of decisive power, coördination of speech, general weakness, and hung

Her husband, a colleague, brought her to me in 1946, for the exclusion of organic disease as the cause mental symptoms. Investigation revealed a true glycæmia, which had been masked for years by barbitur Since recognition of this condition she has had no barbitur Her nervous instability and anxiety disappear immedi after taking sugar. She is fit again to look after her affairs. The blood-sugar, after 50 g. of glucose, showed a at $2^{1}/_{4}$ and $3^{1}/_{4}$ hours to 65 mg. and 60 mg. per 100 ml this stage, the mental symptoms were severe.

ALOPECIA AREATA TREATED WITH THORIU

SIR,—In his paper of Oct. 4 Dr. Feeny has bro forward some valuable observations. It seems, how that one or two points in the assessment of the re and of the value of treatment have not received attention they deserve. The first is the time factor. tendency for alopecia areata to spontaneous recove well known, though growth may often be delayed mo or even years. It seems likely that some at least of success could be accounted for by spontaneous regro Secondly, little is said of the importance of the psy therapeutic effect on the patient of a new treatm

cially with radioactive substances. At least an osphere of encouragement and hope is to be expected h a new procedure. Lastly, the author gives no hint aving considered the possibility that radio-inactive nts and varnishes might produce regrowth of hair as effectively and as quickly as thorium-X in alcohol varnish. Shortly after the appearance of Corsi's er (*Lancet*, 1934, ii, 346) we agreed to try painting s of alopecia in the scalp in equal halves—the one f with thorium-X in alcohol, the other half with the hol vehicle alone. We found in a series of cases that hair grew as quickly and as well in the part which received no thorium, and there was no detectable erence in the response in the two adjacent areas. In ot of one series of 30 cases, thorium-X seemed to e a retarding effect on hair growth, as new hair eared on the untreated halves of the patches some ks earlier than on the sides which had received rium-X.

e realise the difficulties of adequate control of results linical trials, but we do not feel that the evidence n in his paper warrants the conclusion drawn by Feeny that the hair regrew solely, or even chiefly, ause of the thorium used. We both use thorium-X ularly, but no longer for treating alopecia.

Obituary

WILLIAM HENRY KAUNTZE

C.M.G., M.D. MANC., M.B. LOND., F.R.C.P.

r. W. H. Kauntze, medical adviser to the Secretary State for the Colonies, died at Woking on Nov. 4.

orn in Manchester in 1887, the son of Mr. W. G. untze, he was educated at Manchester University also took a London medical degree. After qualifying 1911 he acted as house-surgeon at Manchester Royal rmary and later as resident medical officer at Salford rmary. Shortly before the outbreak of the first world war he entered the Colonial Medical Service, and he served as a medical officer in Nigeria till he was posted to the East Coast when the West African troops were moved there in 1916. With the rank of major he served in the field with distinction, and in 1919 he was appointed senior bacteriologist and deputy director of laboratory services in Kenya. On leave in England he attended the first post-war course in tropical medicine at the London School of Hygiene, taking his D.P.H. in 1921. This enthusiasm for his work was characteristic, and Dr. N. P. Jewell, who collaborated with him in *A ndbook of Tropical Diseases* (1931) writes: "Kauntze died assiduously, keeping up to date by avid reading medical literature, and he had a splendid knowledge his profession. In Kenya, he became very popular, h for his great medical ability and his ready willingness help in trouble."

Lafayette

In 1932 Kauntze was made director of medical services Uganda, and he held this post for nearly ten years. ring this period he interested himself in tropical thology and published a number of papers on dysenteric ccines and their application to the treatment and evention of bacillary dysentery. In 1941 he was called to England to become assistant medical adviser the Colonial Office, and towards the end of 1944 he s appointed chief medical adviser to the Secretary of ate.

After the end of the late war he travelled widely by , visiting Africa, the West Indies, and the Far East. e undertook these fatiguing journeys at the cost of eat pain and discomfort, for he was already a sick an. In his later years he became a sincere student of cial medicine in the tropics, and in 1946 he summarised his views in a valuable article in the *Practitioner*. Clear in ideas and in expression, he was an excellent chairman, and in this capacity served on many committees. Sir Philip Manson-Bahr speaks of his "gentle and particularly attractive character. Kind and considerate to all around him, he loved the service to which he had devoted his life, and no trouble was too much for him in order to improve the conditions of service for his officers."

"A year or two before the war," writes Sir Wilson Jameson, "I had the privilege of travelling through part of Uganda with Dr. and Mrs. Kauntze and of spending some little time with them in their delightful home on the shores of Lake Victoria. I knew Dr. Kauntze before then, but I got to know him much better during my visit to his own territory. He was a first-class director of medical services, and as soon as wartime conditions permitted his release from Uganda, he joined the headquarters staff of the Colonial Office. Ultimately, as chief medical adviser, he was able to press forward with some of the plans on which he had set his heart—the expansion and improvement of the colonial medical schools, the creation of a research organisation, the development of a more preventive outlook in the Service generally. He travelled extensively throughout the colonies, and his wide knowledge was invaluable in the conferences that have been held in connexion with the establishment of a World Health Organisation. He was the most unassuming of men and he never spared himself. His work always took first place. At the meeting of the Interim Commission of the World Health Organisation at Geneva last Easter, when he knew his illness was mortal, his one desire was to complete the task he had set himself. Kauntze has died just when he was most needed by the Service in which he spent his professional life. But his good influence will be felt for years to come. We at the Ministry of Health have lost a very helpful and lovable colleague."

Dr. Kauntze married in 1919 Miss Edith Johnston, of Cape Town, and they had one daughter. He was appointed C.M.G. in 1937, and he was elected F.R.C.P. in 1945. Recently he was made a knight of the Order of St. John of Jerusalem.

Public Health

Poliomyelitis and Polioencephalitis

THE decline in notifications has continued. Those for the week ended Nov. 1 were: poliomyelitis 221 (251) and polioencephalitis 22 (29). The decline of prevalence is, however, much less steep than was the rise; and it now seems probable that for the remainder of the year incidence will remain at a much higher level than is usual in winter.

Infectious Disease in England and Wales

WEEK ENDED NOV. 1

Notifications.—Smallpox, 0; scarlet fever, 1529; whooping-cough, 1037; diphtheria, 178; paratyphoid, 15; typhoid, 4; measles (excluding rubella), 2052; pneumonia (primary or influenzal), 502; cerebrospinal fever, 39; poliomyelitis, 221; polioencephalitis, 22; encephalitis lethargica, 0; dysentery, 126; puerperal pyrexia, 100; ophthalmia neonatorum, 41, relapsing fever, 1. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were no deaths from enteric fever or measles, 1 (0) from scarlet fever, 3 (0) from diphtheria, 4 (1) from whooping-cough, 51 (3) from diarrhœa and enteritis under two years, and 16 (2) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 203 (corresponding to a rate of 26 per thousand total births), including 34 in London.

THE British Standard for Film Strip and Film Slides has been revised. Copies are obtainable, price 2s., from the sales department, British Standards Institution, 24, Victoria Street, London, S.W.1.

Notes and News

EMPIRE MEDICAL ADVISORY BUREAU

THE council of the British Medical Association have made a timely and friendly gesture in setting up this bureau to help doctors from overseas who are visiting this country. A committee of management has already been appointed, and this week applications are invited (in our advertisement columns) for the position of director. When the bureau is in action visitors will be able to turn to it for information about postgraduate study and about suitable lodgings and hotels, as well as for letters of introduction to their British colleagues, both specialists and general practitioners. But it will not be bound by academic and professional limits. To the stranger everyday life in this country must often seem bewildering and intricate; his ration book is in a mysterious code, tickets for the ballet are hard to come by, and he is uncertain where the Derby is run. With all these problems the bureau will lend a helping hand. In short the new director's job will be to enable his visiting colleagues to feel at home and find their way around.

THE SURGEON AND THE ID

A SUCCESSFUL analysis, they say, must be founded on a good "transference" between psycho-analyst and patient. But neurotics, who are as chancy—or as predetermined—in their likings as anybody else, may form their transferences with quite the wrong people. The frustrate young man in Mary Renault's latest book, *Return to Night*,[1] chooses a surgeon. Luckily for him she has read some psychology, and when not being pompous about her work (a weakness not entirely confined to surgeons, after all) is a mature and pleasant person. The young man has been hamstrung for any part in real life by his deep attachment to his mother and by the love and hate she bears him.

Here, then, are materials for a psychological study of two people whose love for each other is hampered by disparity of years (the surgeon is much the older), old bondage, unfamiliar crises, and purely practical obstructions—ample material, little of which is wasted. But the discontented Miss Renault throws in all sorts of extras—underground caves, fighting drunks, calumny, runaway horses, and finally an unlikely premarital experience for the frigid mother. What do we want with these Jane Eyre-ish accessories? Her characters, caught in their inward web, are living at many levels; their conversations are haunted with overtones; they are forever blundering and trespassing, healing, and restoring. But, into this personal adventure, drama keeps breaking so destructively that Miss Renault has to summarise whole phases; and indeed at her tenth chapter, in a few pages of bald exposition, reduces her own carefully wrought mystery to dust. Her trouble is that she doesn't know how well she writes. The book, however, has been awarded the Metro-Goldwyn-Mayer prize of £40,000 as the outstanding novel of the year, and will shortly be filmed. No doubt the caves and so forth will prove a Metro-goldmine.

BY WOMEN FOR WOMEN

SMALL and intimate, staffed entirely by women, the Marie Curie Hospital occupies a Victorian house in Fitzjohn's Avenue, Hampstead. The original hospital, founded in 1929, for the treatment of women with cancer, by the London Association of the Medical Women's Federation, was destroyed by a bomb in 1944, and this second building was opened in May, 1946, with 11 beds. On Oct. 22 when H.R.H. the Duchess of Gloucester opened the new nurses' home, Lady Moran, the chairman of the board of management, was able to announce that there are now some 50–60 beds in action, and that, when times allow, it is hoped to build a new hospital on the old site which will bring the full complement of beds up to 100. Fortunately the Helen Chambers research laboratory was undamaged. Since 1944, when an appeal was launched after the bombing, the hospital has received donations to the value of £120,000 from the public, and has been able to acquire, besides the new hospital building, two new houses to receive nurses and domestic staff, and another house in Fitzjohn's Avenue which will be used by ambulatory and convalescent patients, thus sparing beds in the main hospital.

The new nurses' home, also a Victorian building, same friendly and intimate quality as the rooms, of various shapes and sizes, with a unexpected differences of structure, decoration, eq and outlook, gain fresh individuality from the taste owners; nothing could be less institutional or The whole building is well warmed, and there are kitchens, a roomy pantry where the sisters can make do their ironing, a large comfortable sitting-room, pleasant garden.

Sir William Douglas, secretary of the Ministry of who replied to the Duchess of Gloucester's good the future of the hospital and of the new nurses' advised all donors to give at once, since money given the appointed day will be used for the individual on which it is bestowed. Alderman Mrs. R. S. G. the mayor of Hampstead, spoke of the hope of discoveries in the research department of the ho

CHRISTMAS SEALS

THE National Association for the Prevention of Tub has growing commitments: the number of Colonial scholarships for doctors and other health workers has increased, and last July a conference held in London attended by over a thousand delegates. For the contin of its work the association looks largely to proceeds the sale of its Christmas seals, from which source £250,000 has been obtained in the last ten years. This the seals, presented as in previous years by the Can Tuberculosis Association, depict in cheerful colours a te oxen bringing home the Yule log. The seals may be ob at a cost of 4*s*. per sheet of 100, from the Duchess of P Chairman N.A.P.T., Tavistock House North, T Square, London, W.C.1.

EARTH-EATING

IT is hard to see why the idea of earth-eating repulsion, whereas the prospect of eating a dead animal unobjectionable—pleasant, indeed. Patients will chalk or kaolin without demur when earth in such prescribed by the physician; and minerals derived earth, such as salt, iron, and mercury, rouse no distaste offered in food or medicaments: and what is a barium but geophagy? No doubt the mother's horrified convi that earth-eating is "dirty" makes a strong impression the young child; and the association of pica with *disorders and with parasitic infestations* later heightens disgust.

Yet in many parts of the world, as Robertson[1] poi out, earth is eaten either for medicinal reasons or as a ferti rite. He quotes Dr. Leonhart Ranwolf, who in the sixte century noted that the women of Tripoli ate an earth ca *jusabar*. Sir *George Watt found the same* practices in In in 1908. A comestible clay, found near Koluth, is sold in t bazaars to improve the complexion. The edible earth commonly eaten is said to be a light yellow ochre, ca *multani mitti*, which is taken in doses of about gr. 5–30 relieve acidity of the stomach. Other edible earths are *Sang Basri*, imported *from the Persian* Gulf and used in to preparations; a sweet-scented earth called *Sausrastra mitti* given as an astringent for internal bleeding; and the g stone, made from fine fuller's earth, compressed into th form of a large egg and scented and gilded, a little of which scraped off and taken in water as a remedy for many disorder Potter's earth *for eating* is sold in the Calcutta bazaar partly baked saucer-shaped chips about 2 in. in diamet Robertson considers that most of the earths eaten in Ind are fuller's earth containing the clay mineral montmorilloni as well as some silica.

The "Samian stone" mentioned by Pliny, betw A.D. *23 and 79, is thought to have been* a compact for of kaolinite such as lithomarge. Chaucer mentions " armoniac," or Armenian earth, which was used as an antid for poison, and for stanching wounds. This early reputati of adsorbent earths received scientific confirmation as late as 1914, when J. A. Lloyd reported that the fi *particles of fuller's earth would remove* alkaloids from so tion; and the next year B. Fantus noted that fuller's ear was beneficial in cases of morphine, nicotine, and ipecacuan ning, and even—though to a lesser extent—in poisoning strychnine and aconitine. Some fuller's earths are more tive than others; and of English earths, those from hill, Surrey, and from the neighbourhood of Bath are the t adsorbent.

he two main types of clay used in medicine—fuller's h and kaolin—are often thought to be identical but in fact quite distinct both mineralogically and in physical erties.

---

versity of Cambridge

n Nov. 1 the following degrees were conferred:

A.—R. M. Fry.

D.—Edward Clayton-Jones, C. R. T. Lane, R. T. Mummery, . Nicholson, P. D. Scott, W. H. K. Willis.

. J. Hoogstraten has been appointed to an Elmore ical research studentship.

versity of Edinburgh

n Oct. 25 the following degrees and diplomas were erred:

D. (in the faculty of medicine).—Y. Y. Akrawi.

Sc. (second-class honours).—G. A. C. Summers.

P.H.—*K. A. Brahmabhatt, *V. D. R. Martin, *J. A. Miller.

M.R.—*T. A. B. Mason.

* In absentia.

al College of Physicians of Edinburgh

t a meeting of the college held on Nov. 4, with Dr. D. M. n, the president, in the chair, the following were introed and took their seats as fellows:

M. D. Shepherd (Shanklin, I.o.W.), P. M. Wood (Halifax), h Craig (Aberdeen), J. McG. Rogan (Glasgow), J. M. Macfie inburgh), A. W. Wright (Edinburgh), Charles Cameron (Edinh), Neil Macmichael (Edinburgh), J. A. L. Gilbert (Edinburgh).

he following were elected fellows:

D. M. Claassens (Cape Town), J. M. Watt (Johannesburg), Sutherland (Edinburgh), Gurbuxsh Singh (Amritsar, India), Gillhespy (Paisley), J. G. Macleod (Edinburgh), G. M. Wilson nburgh), R. S. Aitken (Aberdeen), T. G. Brown (Hamilton).

he following were elected members:

H. Rose, K. G. W. James, A. S. R. Stewart, Jack Rudolph, Ross, J. B. H. MacArthur, I. H. L. Gillies, H. J. T. Ross, J. G. Barrie, W. G. MacDougall, J. W. Rae, K. K. Datey, Heller, H. G. H. Richards, J. K. Drummond, H. G. H. hton, Niels Pedersen, P. E. Brown, J. W. Buchanan, M. W. dall, Thomas Black, G. B. Tait, A. W. O. Taylor, D. E. Williams, rin Hughes, W. L. Sharp, Alexander Skene, H. R. L. Fraser, Horne, J. B. Lowe, H. D. Ross, Erich Kahn, Malcolm Watt, Claireaux, J. W. T. Pretsell, A. G. Harper, T. McS. Wilson, Das, H. C. W. Stringer, J. T. R. Russell, Constance C. Forsyth.

he Freeland Barbour fellowship for original investigations ied out in the laboratory of the college was awarded to t.-Colonel W. F. Harvey.

al College of Surgeons of England

ir William H. Collins professorship of human and comtive pathology.—The council invites applications for this r. The salary will be not less than £2000 per annum, particulars may be had from the secretary. Applications the names of two referees must reach the college, coln's Inn Fields, London, W.C.2, not later than Dec. 31.

he museum of the college in Lincoln's Inn Fields, London, .2, is again open to doctors and medical students daily n 10 A.M. to 5 P.M. (1 P.M. on Saturdays), but owing to tage of accommodation the anatomy museum is somees in use during the afternoon for lectures. The collections still much depleted by enemy action, but the following es are sufficiently complete for exhibition:

natomy: specimens illustrating the nervous system and ument are arranged and labelled; specimens illustrating other ems are available for study, but are not yet permanently nged or labelled.

athology: diseases of the skeleton, nervous system, and alimensystem; teratology; and a special group of selected Hunterian imens.

dical War Relief Fund

he committee of this fund has decided that it is unnecessary supporters to send further contributions, as applications assistance are now relatively infrequent. Though some he present beneficiaries are likely to need help for some rs, the committee is satisfied that, by the time the existing ance of some £24,000 has been exhausted, the fund will e discharged the temporary function for which it was blished. The committee expresses its gratitude for the port received from the profession at home and overseas ing the past seven years.

Royal Faculty of Physicians and Surgeons of Glasgow

The following office bearers have been elected for the ensuing year: president, Dr. G. B. Fleming; visitor, Dr. W. R. Snodgrass; treasurer, Mr. W. W. Galbraith; librarian, Dr. A. L. Goodall; representative on the General Medical Council, Mr. Andrew Allison; councillors, Mr. D. McKay Hart, Mr. A. B. Kerr, Mr. J. H. MacDonald, Mr. E. G. Oastler, Mr. Charles Read, Mr. W. A. Sewell, Mr. G. H. Stevenson, Mr. Matthew White, Dr. G. M. Wishart, Dr. J. H. Wright.

London School of Hygiene

The following awards have been made to students of the course for the academic diploma in public health held at the school during the session 1946–47:

Chadwick prize.—Dr. J. H. F. Brotherston.

Association of Industrial Medical Officers prize.—Dr. J. N. Morris.

Hecht prize.—Dr. M. E. R. Balfour and Dr. T. McL. Galloway.

Industrial Health Congress

The ninth International Congress on Industrial Health will be held in England from Sept. 12 to 17, 1948. The secretary of the congress may be addressed at 14, Hobart Place, London, S.W.1.

Immunisation against Influenza in U.S. Army

All personnel of the United States Army are being inoculated against influenza. In addition to the A and B viruses, the vaccine contains an A variant cultured last season during a distinctive type of outbreak in New Jersey. Laboratory tests will be made in the field to establish outbreaks.

Chloroform Centenary

To mark the centenary of Sir James Young Simpson's discovery of chloroform in Edinburgh on Nov. 4, 1847, the university conferred the honorary degree of LL.D. on Dr. H. W. Featherstone, founder-president of the Association of Anæsthetists, and on Sheriff T. B. Simpson, a grand-nephew of the discoverer. The celebrations, reported in the *Scotsman* of Nov. 5, included a lecture by Dr. Douglas Guthrie.

Cancer Control Programme

A scheme for the twice-yearly examination of all women over the age of 40 is reported by B.U.P. to have been approved by the Delaware division of the American Cancer Society. For the examination, which is to be of the breasts and pelvic organs, the charge will be $3; but those who cannot afford to pay will be helped from the society's funds.

St. Leonard's Hospital, Shoreditch

The Minister of Health has appointed Mr. V. Zachary Cope, F.R.C.S., and Miss M. F. Dykes, S.R.N., to hear on Nov. 18 an appeal made by the London County Council against the decision of the General Nursing Council to withdraw recognition of this hospital as a training school for nurses. As reported last week (*Lancet*, Nov. 8, p. 704) 33 doctors have signed a memorandum regarding the threatened closure of the inpatient wards at the hospital as a result of the withdrawal of recognition.

U.S. Atomic Energy Commission

Dr. Shields Warren has been appointed interim director of this commission's new division of biology and medicine. Dr. Warren is director of the Massachusetts State Tumor Diagnosis Service and assistant professor of pathology at Harvard University. The division will correlate programmes of medical and biological research and will direct the commission's health physics work and industrial hygiene activities.

Royal Institute of Public Health and Hygiene

Prof. E. D. Adrian, O.M., F.R.S., will deliver the Harben lectures at the institute, 28, Portland Place, London, W.1, at 3 P.M., on Monday, Tuesday, and Wednesday, Dec. 15, 16, and 17. The title of the series is the Organisation of the Nervous System, and in the three lectures he will deal with the elements of nervous activity, the effects of the sense organs, and the activity of the brain.

International Organisation against Trachoma

At a meeting of this organisation's executive committee in Paris last May it was decided that the next general assembly should be held in London in 1950. Publication of the organisation's quarterly journal, the *Revue Internationale du Trachome*, suspended in the war, is to be resumed shortly. Further information may be had from the president, Mr. A. F. MacCallan, F.R.C.S., Westminster Hospital Medical School, 17, Horseferry Road, London, S.W.1.

What do we want with these Jane Eyre-ish accessories? Her characters, caught in their inward web, are living at many levels; their conversations are haunted with overtones; they are forever blundering and trespassing, healing, and restoring. But, into this personal adventure, drama keeps breaking so destructively that Miss Renault has to summarise whole phases; and indeed at her tenth chapter, in a few pages of bald exposition, reduces her own carefully wrought mystery to dust. Her trouble is that she doesn't know how well she writes. The book, however, has been awarded the Metro-Goldwyn-Mayer prize of £40,000 as the outstanding novel of the year, and will shortly be filmed. No doubt the caves and so forth will prove a Metro-goldmine.

BY WOMEN FOR WOMEN

Small and intimate, staffed entirely by women, the Marie Curie Hospital occupies a Victorian house in Fitzjohn's Avenue, Hampstead. The original hospital, founded in 1929, for the treatment of women with cancer, by the London Association of the Medical Women's Federation, was destroyed by a bomb in 1944, and this second building was opened in May, 1946, with 11 beds. On Oct. 22 when H.R.H. the Duchess of Gloucester opened the new nurses' home, Lady Moran, the chairman of the board of management, was able to announce that there are now some 50–60 beds in action, and that, when times allow, it is hoped to build a new hospital on the old site which will bring the full complement of beds up to 100. Fortunately the Helen Chambers research laboratory was undamaged. Since 1944, when an appeal was launched after the bombing, the hospital has received donations to the value of £120,000 from the public, and has been able to acquire, besides the new hospital building, two new houses to receive nurses and domestic staff, and another house in Fitzjohn's Avenue which will be used by ambulatory and convalescent patients, thus sparing beds in the main hospital.

The new nurses' home, also a Victorian building, same friendly and intimate quality as the hospit rooms, of various shapes and sizes, with agreeab unexpected differences of structure, decoration, equ and outlook, gain fresh individuality from the taste owners; nothing could be less institutional or ste. The whole building is well warmed, and there are kitchens, a roomy pantry where the sisters can make do their ironing, a large comfortable sitting-room, pleasant garden.

Sir William Douglas, secretary of the Ministry of who replied to the Duchess of Gloucester's good wi the future of the hospital and of the new nurse advised all donors to give at once, since money given the appointed day will be used for the individual on which it is bestowed. Alderman Mrs. R. S. G. C the mayor of Hampstead, spoke of the hope of discoveries in the research department of the hospital.

CHRISTMAS SEALS

The National Association for the Prevention of Tub has growing commitments: the number of Colonial scholarships for doctors and other health workers has increased, and last July a conference held in London attended by over a thousand delegates. For the contin of its work the association looks largely to procee the sale of its Christmas seals, from which source £250,000 has been obtained in the last ten years. This the seals, presented as in previous years by the Can Tuberculosis Association, depict in cheerful colours a te oxen bringing home the Yule log. The seals may be ob at a cost of 4s. per sheet of 100, from the Duchess of Chairman N.A.P.T., Tavistock House North, Tav Square, London, W.C.1.

EARTH-EATING

It is hard to see why the idea of earth-eating repulsion, whereas the prospect of eating a dead animal unobjectionable—pleasant, indeed. Patients will chalk or kaolin without demur when earth in such f prescribed by the physician; and minerals derived from earth, such as salt, iron, and mercury, rouse no distaste offered in food or medicaments: and what is a barium but geophagy? No doubt the mother's horrified com that earth-eating is "dirty" makes a strong impression the young child; and the association of pica with disorders and with parasitic infestations later heightens disgust.

Yet in many parts of the world, as Robertson[1] poi out, earth is eaten either for medicinal reasons or as a ferti rite. He quotes Dr. Leonhart Rauwolf, who in the sixte century noted that the women of Tripoli ate an earth c *jusabar*. Sir George Watt found the same practices in In in 1908. A comestible clay, found near Koluth, is sold in bazaars to improve the complexion. The edible earth m commonly eaten is said to be a light yellow ochre, c *multani mitti*, which is taken in doses of about gr. 5–30 relieve acidity of the stomach. Other edible earths are *Sang Basri*, imported from the Persian Gulf and used in to preparations; a sweet-scented earth called *Saurashtra mritt* given as an astringent for internal bleeding; and the g stone, made from fine fuller's earth, compressed into th form of a large egg and scented and gilded, a little of which scraped off and taken in water as a remedy for many disorders. Potter's earth for eating is sold in the Calcutta bazaar partly baked saucer-shaped chips about 2 in. in diamete Robertson considers that most of the earths eaten in In are fuller's earth containing the clay mineral montmorillonite as well as some silica.

The "Samian stone" mentioned by Pliny, betw A.D. 23 and 79, is thought to have been a compact for of kaolinite such as lithomarge. Chaucer mentions "b armoniac," or Armenian earth, which was used as an antid for poison, and for staunching wounds. This early reputati of adsorbent earths received scientific confirmation as late as 1914, when J. A. Lloyd reported that the fi particles of fuller's earth would remove alkaloids from sol tion; and the next year B. Fantus noted that fuller's earth was beneficial in cases of morphine, nicotine, and ipecacuan ning, and even—though to a lesser extent—in poisoning strychnine and aconitine. Some fuller's earths are more tive than others; and of English earths, those from Hill, Surrey, and from the neighbourhood of Bath are the adsorbent.

e two main types of clay used in medicine—fuller's h and kaolin—are often thought to be identical but in fact quite distinct both mineralogically and in physical rties.

versity of Cambridge

n Nov. 1 the following degrees were conferred

_A._—R. M. Fry.

_D._—Edward Clayton-Jones, C. R. T. Lane, R. T. Mummery, L. Nicholson, P. D. Scott, W. H. K. Willis.

r. J. Hoogstraten has been appointed to an Elmore cal research studentship.

versity of Edinburgh

n Oct. 25 the following degrees and diplomas were erred:

D. (in the faculty of medicine).—Y. Y. Akrawi.

Sc. (second-class honours).—G. A. C. Summers.

_P.H._—*K. A. Brahmabhatt, *V. D. R. Martin, *J. A. Miller.

_M.R._—*T. A. B. Mason.

* In absentia.

al College of Physicians of Edinburgh

a meeting of the college held on Nov. 4, with Dr. D. M. n, the president, in the chair, the following were introed and took their seats as fellows:

M. D. Shepherd (Shanklin, I.o.W.), P. M. Wood (Halifax), Craig (Aberdeen), J. McG. Rogan (Glasgow), J. M. Macfie burgh), A. W. Wright (Edinburgh), Charles Cameron (Edin), Neil Macmichael (Edinburgh), J. A. L. Gilbert (Edinburgh).

e following were elected fellows:

D. M. Claassens (Cape Town), J. M. Watt (Johannesburg), Sutherland (Edinburgh), Gurbuxsh Singh (Amritsar, India), Gillhespy (Paisley), J. G. Macleod (Edinburgh), G. M. Wilson burgh), R. S. Aitken (Aberdeen), T. G. Brown (Hamilton).

e following were elected members:

T. H. Rose, K. G. W. James, A. S. R. Stewart, Jack Rudolph, A. Ross, J. B. H. MacArthur, I. H. L. Gillies, H. J. T. Ross, J. G. Barrie, W. G. MacDougall, J. W. Rae, K. K. Datey, M. Heller, H. G. H. Richards, J. K. Drummond, H. G. H. ghton, Niels Pedersen, P. E. Brown, J. W. Buchanan, M. W. dall, Thomas Black, G. B. Tait, A. W. O. Taylor, D. E. Williams, am Hughes, W. L. Sharp, Alexander Skene, H. R. L. Fraser, W. Horne, J. B. Lowe, H. D. Ross, Erich Kahn, Malcolm Watt, E. Caireaux, J. W. T. Pretsell, A. G. Harper, T. McS. Wilson, K. Das, H. C. W. Stringer, J. T. R. Russell, Constance C. Forsyth.

The Freeland Barbour fellowship for original investigations ried out in the laboratory of the college was awarded to ut-Colonel W. F. Harvey.

oyal College of Surgeons of England

Sir William H. Collins professorship of human and comative pathology.—The council invites applications for this air. The salary will be not less than £2000 per annum, nd particulars may be had from the secretary. Applications ith the names of two referees must reach the college, ncoln's Inn Fields, London, W.C.2, not later than Dec. 31.

The museum of the college in Lincoln's Inn Fields, London, W.C.2, is again open to doctors and medical students daily om 10 A.M. to 5 P.M. (1 P.M. on Saturdays), but owing to ortage of accommodation the anatomy museum is sometimes in use during the afternoon for lectures. The collections re still much depleted by enemy action, but the following ries are sufficiently complete for exhibition:

Anatomy: specimens illustrating the nervous system and tegument are arranged and labelled; specimens illustrating other stems are available for study, but are not yet permanently ranged or labelled.

Pathology: diseases of the skeleton, nervous system, and alimentary system; teratology; and a special group of selected Hunterian specimens.

edical War Relief Fund

The committee of this fund has decided that it is unnecessary for supporters to send further contributions, as applications for assistance are now relatively infrequent. Though some of the present beneficiaries are likely to need help for some years, the committee is satisfied that, by the time the existing balance of some £24,000 has been exhausted, the fund will have discharged the temporary function for which it was established. The committee expresses its gratitude for the support received from the profession at home and overseas during the past seven years.

Royal Faculty of Physicians and Surgeons of Glasgow

The following office bearers have been elected for the ensuing year: president, Dr. G. B. Fleming; visitor, Dr. W. R. Snodgrass; treasurer, Mr. W. W. Galbraith; librarian, Dr. A. L. Goodall; representative on the General Medical Council, Mr. Andrew Allison; councillors, Mr. D. McKay Hart, Mr. A. B. Kerr, Mr. J. H. MacDonald, Mr. E. G. Oastler, Mr. Charles Read, Mr. W. A. Sewell, Mr. G. H. Stevenson, Mr. Matthew White, Dr. G. M. Wishart, Dr. J. H. Wright.

London School of Hygiene

The following awards have been made to students of the course for the academic diploma in public health held at the school during the session 1946–47:

Chadwick prize.—Dr. J. H. F. Brotherston.

Association of Industrial Medical Officers prize.—Dr. J. N. Morris.

Hecht prize.—Dr. M. E. R. Balfour and Dr. T. McL. Galloway.

Industrial Health Congress

The ninth International Congress on Industrial Health will be held in England from Sept. 12 to 17, 1948. The secretary of the congress may be addressed at 14, Hobart Place, London, S.W.1.

Immunisation against Influenza in U.S. Army

All personnel of the United States Army are being inoculated against influenza. In addition to the A and B viruses, the vaccine contains an A variant cultured last season during a distinctive type of outbreak in New Jersey. Laboratory tests will be made in the field to establish outbreaks.

Chloroform Centenary

To mark the centenary of Sir James Young Simpson's discovery of chloroform in Edinburgh on Nov. 4, 1847, the university conferred the honorary degree of LL.D. on Dr. H. W. Featherstone, founder-president of the Association of Anæsthetists, and on Sheriff T. B. Simpson, a grand-nephew of the discoverer. The celebrations, reported in the _Scotsman_ of Nov. 5, included a lecture by Dr. Douglas Guthrie.

Cancer Control Programme

A scheme for the twice-yearly examination of all women over the age of 40 is reported by B.U.P. to have been approved by the Delaware division of the American Cancer Society. For the examination, which is to be of the breasts and pelvic organs, the charge will be $3; but those who cannot afford to pay will be helped from the society's funds.

St. Leonard's Hospital, Shoreditch

The Minister of Health has appointed Mr. V. Zachary Cope, F.R.C.S., and Miss M. F. Dykes, S.R.N., to hear on Nov. 18 an appeal made by the London County Council against the decision of the General Nursing Council to withdraw recognition of this hospital as a training school for nurses. As reported last week (_Lancet_, Nov. 8, p. 704) 33 doctors have signed a memorandum regarding the threatened closure of the inpatient wards at the hospital as a result of the withdrawal of recognition.

U.S. Atomic Energy Commission

Dr. Shields Warren has been appointed interim director of this commission's new division of biology and medicine. Dr. Warren is director of the Massachusetts State Tumor Diagnosis Service and assistant professor of pathology at Harvard University. The division will correlate programmes of medical and biological research and will direct the commission's health physics work and industrial hygiene activities.

Royal Institute of Public Health and Hygiene

Prof. E. D. Adrian, O.M., F.R.S., will deliver the Harben lectures at the institute, 28, Portland Place, London, W.1, at 3 P.M., on Monday, Tuesday, and Wednesday, Dec. 15, 16, and 17. The title of the series is the Organisation of the Nervous System, and in the three lectures he will deal with the elements of nervous activity, the effects of the sense organs, and the activity of the brain.

International Organisation against Trachoma

At a meeting of this organisation's executive committee in Paris last May it was decided that the next general assembly should be held in London in 1950. Publication of the organisation's quarterly journal, the _Revue Internationale du Trachome_, suspended in the war, is to be resumed shortly. Further information may be had from the president, Mr. A. F. MacCallan, F.R.C.S., Westminster Hospital Medical School, 17, Horseferry Road, London, S.W.1.

Notes and News

EMPIRE MEDICAL ADVISORY BUREAU

THE council of the British Medical Association have made a timely and friendly gesture in setting up this bureau to help doctors from overseas who are visiting this country. A committee of management has already been appointed, and this week applications are invited (in our advertisement columns) for the position of director. When the bureau is in action visitors will be able to turn to it for information about postgraduate study and about suitable lodgings and hotels, as well as for letters of introduction to their British colleagues, both specialists and general practitioners. But it will not be bound by academic and professional limits. To the stranger everyday life in this country must often seem bewildering and intricate; his ration book is in a mysterious code, tickets for the ballet are hard to come by, and he is uncertain where the Derby is run. With all these problems the bureau will lend a helping hand. In short the new director's job will be to enable his visiting colleagues to feel at home and find their way around.

THE SURGEON AND THE ID

A SUCCESSFUL analysis, they say, must be founded on a good "transference" between psycho-analyst and patient. But neurotics, who are as chancy—or as predetermined—in their likings as anybody else, may form their transferences with quite the wrong people. The frustrate young man in Mary Renault's latest book, *Return to Night*,[1] chooses a surgeon. Luckily for him she has read some psychology, and when not being pompous about her work (a weakness not entirely confined to surgeons, after all) is a mature and pleasant person. The young man has been hamstrung for any part in real life by his deep attachment to his mother and by the love and hate she bears him.

Here, then, are materials for a psychological study of two people whose love for each other is hampered by disparity of years (the surgeon is much the older), old bondage, unfamiliar crises, and purely practical obstructions—ample material, little of which is wasted. But the discontented Miss Renault throws in all sorts of extras—underground caves, fighting drunks, calumny, runaway horses, and finally an unlikely premarital experience for the frigid mother. What do we want with these Jane Eyre-ish accessories? Her characters, caught in their inward web, are living at many levels; their conversations are haunted with overtones; they are forever blundering and trespassing, healing, and restoring. But, into this personal adventure, drama keeps breaking so destructively that Miss Renault has to summarise whole phases; and indeed at her tenth chapter, in a few pages of bald exposition, reduces her own carefully wrought mystery to dust. Her trouble is that she doesn't know how well she writes. The book, however, has been awarded the Metro-Goldwyn-Mayer prize of £40,000 as the outstanding novel of the year, and will shortly be filmed. No doubt the caves and so forth will prove a Metro-goldmine.

PATHOLOGY OF SUDDEN DEATH *

KEITH SIMPSON
M.D. Lond.
CTURER IN FORENSIC MEDICINE, GUY'S HOSPITAL, LONDON

This review of the more common pathology of sudden ath is based on an analysis of my own medicolegal se-records of 15,000 necropsies, ranging from simple tural deaths to violent wilful killing, and covering all es from birth to that of a man who claimed 108 years a slight exaggeration into which he had been flattered r press attentions.

The proportion of deaths from natural causes was %, roughly two-thirds, a reminder of the vast amount ordinary morbid anatomy passing through the hands the forensic pathologist. Among these 15,000 natural aths were 6267 (41%) in which death took place ddenly, if not instantaneously, on collapse, an unexcted event precipitating death within a few hours of parently good health. This group I have extracted r study, and I make no apology for concentrating on e principal common disorders rather than the rarer more diverting diseases. I have excluded the hazards birth, such as atelectasis of the lung, and developmental fects which could not properly be included within the rin of disease, for these are problems in other fields.

Cause of Death.—A personal factor must enter into e wording of the cause of death. Where, for instance, ility, hypertension, and coronary occlusion by eroma exist together at death, as is common enough, is reasonable to assume that all three have contributed death. The heading used for such cases has depended the relative contribution assessed for each disease, d in such a matter I have to ask you to trust to my aluation, right or wrong. As age increases, its contriution to the decompensation of a heart which has eld hypertension at bay for many years must gradually ncrease also; it must become increasingly reasonable to ay that senility is the cause of such a death. However, this is a human whim, not measurable, which makes broader statistics of this kind unsuitable for mathematical eories.

The field covered is indicated in the accompanying table. It is a striking feature of the complete table that, among the common natural causes of sudden death, the failings of the coronary or cerebral arteries alone account for more than 56%. These, unlike the failings of the aorta or of heart valves, rest on the ravages of disease or of what Clifford Allbutt has called the "qualities of tissues carried away by the stealthy hours" for which medicine has no known treatment—a sobering thought which might well stimulate new interest in the pathogenesis of arterial sclerosis.

ACUTE ADRENAL INSUFFICIENCY

Ten years ago, in an Erasmus Wilson lecture, I discussed the pathology of the fatal syndrome of acute adrenal insufficiency, finding examples of the diseases recognised to erase the functioning adrenal rapidly enough to cause death within a few hours (Simpson 1937). The most common is undoubtedly bilateral spontaneous hæmorrhage; and, whereas those hæmorrhages which occur after infancy are still recognised as being largely the result of meningococcal or streptococcal septicæmia (the former in cerebrospinal fever as the Waterhouse-Friderichsen syndrome). those which arise in the few days or weeks after birth have subsequently been recognised as commonly due to erythroblastosis fœtalis and not to the exaggerated hyperæmia of the androgenic zone in the postnatal period. Acute caseous tuberculosis and metastatic deposits of malignant growth comprise most of the remainder. Willis (1934) drew attention to the frequency of massive bilateral metastases in the suprarenal glands, especially from growths of the bronchus and breast. Many observers have confirmed his figure of some 9–10% for the frequency of adrenal involvement in all cases of metastatic cancer, and bilateral involvement is as common as unilateral.

RUPTURE OF AORTA WITHOUT ANEURYSM

Aortic rupture is as common without aneurysm as with it—indeed, increasingly more common—and the stimulus of Shennan's monograph (1934) has led to a more critical examination of many ruptures which might at first sight appear to result from the atheroma that is likely to be present (whatever the cause of rupture) after the age of 40.

Hyaline change—fatty atrophy of the medial muscle, mucinoid and hyaline degeneration of the connective tissue, and fragmentation of the elastin—is more common in men (65% males and 35% females in Shennan's original series), and, like all vascular ruptures, is aggravated by hypertension.

The ascending aorta gives way more often than any other part; in about four-fifths of my own 160 cases the burst took place between the aortic valve and the origin of the innominate artery. Hyaline degeneration was responsible for 60% of these.

The reporting of dissecting aneurysm has lagged behind that of rupture without aneurysm simply because though some degree of dissection is almost invariable—as a rule between the media and adventitia—it is usually short, being cut short by rupture into the pericardium. Nevertheless some remarkably long dissections have been recorded, and I have on many occasions traced the

ANALYSIS OF MORE COMMON NATURAL CAUSES OF SUDDEN DEATH

Cause of death	No. of cases	Pathological analysis
Abortion (natural) ..	10

* A lecture delivered to the Royal College of Surgeons on July 29, 1947.

London Medical Exhibition

This exhibition will be held at the Horticultural Hall, Vincent Square, London, S.W.1, from Nov. 17 to 21.

Return to Practice

The Central Medical War Committee announces that Dr. HAROLD PARSONS has resumed civilian practice at 25, Upper Wimpole Street, London, W.1 (Welbeck 9083).

Harveian Society of London

The late Sir Norman Gray Hill, who was killed in Sicily in 1944 while serving with the R.A.M.C., has left half the residue of his estate to this society.

Dr. G. S. W. Organe, consultant anæsthetist to Westminster Hospital, is making a three weeks' lecture tour of Italy on behalf of the British Council.

An expert committee set up by the Interim Commission of the World Health Organisation hopes to publish next year the first draft of an international pharmacopœia (*W.H.O. Chronicle*, 1947, **1**, 149).

The first number of a new quarterly, the *Journal of Clinical Pathology*, has appeared this month. Edited for the Association of Clinical Pathologists by Dr. A. Gordon Signy, the journal is published by the British Medical Association. The annual subscription is 25*s.*, and single numbers are obtainable for 7*s.* 6*d.*

Appointments

PHILPS, SEYMOUR, F.R.C.S.: asst. ophthalmic surgeon, St. Bartholomew's Hospital, London.
ROTH, MARTIN, M.D. Lond., M.R.C.P.: senior psychiatrist, Crichton Royal Mental Hospital, Dumfries.
SIGNY, A. G., M.B. Lond.: pathologist, group laboratory, St. Mary Abbots Hospital, Kensington.
STUART, R. D., D.SC., M.D. Aberd., D.P.H.: bacteriologist, Glasgow Royal Infirmary.
USBORNE, MARY, M.B. Lond., M.R.C.P., D.C.H.: house-physician, Hospital for Sick Children, Great Ormond Street, London.

The London Hospital:

AYOUB, J. E. M., B.M. Oxfd, F.R.C.S.: asst. ophthalmic surgeon.
CHALLIS, J. H. T., M.R.C.S., D.A.: senior anæsthetist.
FOX, G. P., M.A. Camb., M.R.C.S., D.A.: asst. anæsthetist.
LISTER, ARTHUR, M.B. Camb., F.R.C.S.: senior ophthalmic surgeon.

Births, Marriages, and Deaths

BIRTHS

CHAPMAN.—On Nov. 5, at Chipping Norton, the wife of Dr. John Chapman—a son.
CRAIG.—On Nov. 1, at York, the wife of Mr. A. J. Craig, F.R.C.S.—a son.
EMBLETON.—On Nov. 7, at Wokingham, the wife of Dr. J. J. A. Embleton—a son.
FOSTER-CARTER.—On Nov. 7, in London, the wife of Dr. A. F. Foster-Carter—a son.
HARTLEY.—On Nov. 6, at Loughborough, the wife of Dr. P. L. M. Hartley—a son.
MCGOWAN.—On Nov. 4, at Bristol, the wife of Dr. G. K. McGowan—a daughter.
MOIR.—On Nov. 4, at Woking, the wife of Dr. J. H. Moir—a son.
MOORE.—On Nov. 3, the wife of Dr. T. S. Moore—a son.
SIMMONS.—On Nov. 1, at Andover, the wife of Dr. A. B. Simmons—a daughter.
WICKES.—On Nov. 2, at Plaxtol, Kent, the wife of Dr. I. G. Wickes—a daughter.
WRIGHT.—On Nov. 2, the wife of Dr. H. B. Wright—a son.

MARRIAGES

CARTER—GRANTHAM.—On Nov. 1, in London, Frederick Stephen Carter, M.B., to Nym Grantham.
FINCH—FELDMAN.—On Nov. 4, in London, Bernard Finch, M.R.C.S., to Patricia Feldman.
FLANAGAN—PAYNE.—On Nov. 7, in London, Michael Brendan Flanagan, M.B., to Vera Doreen Payne.
VINCENT—VENTOR.—On Nov. 8, at Transkei, S. Africa, S. E. Vincent, M.R.C.S., to Joyce Ventor.
WOLFSON—ESCHELBACHER.—On Oct. 29, in London, Leslie Joseph Wolfson, M.B., to Nancy Eschelbacher.

DEATHS

BARNES.—On Nov. 1, at Colyton, Devon, Henry John Barnes, M.R.C.P.E., lieut.-colonel R.A.M.C. retd., aged 89.
ROBERTS.—On Nov. 7, at Folkestone, Hugh Treharne Llewellyn Roberts, M.A. Camb., L.R.C.P.E., barrister at law, aged 80.
STRICKLAND.—On Nov. 3, at St. Helier, Jersey, Cyril Strickland, M.A., M.D. Camb., aged 66.
WHITE.—On Nov. 9, John Richard White, L.R.C.P.E., aged 89.
WILLIAMS.—On Oct. 29, at Killiney, Herbert Armstrong Williams, D.S.O., lieut.-colonel I.M.S. retd., aged 72.

PATHOLOGY OF SUDDEN DEATH *

KEITH SIMPSON
M.D. Lond.
CTURER IN FORENSIC MEDICINE, GUY'S HOSPITAL, LONDON

This review of the more common pathology of sudden ath is based on an analysis of my own medicolegal se-records of 15,000 necropsies, ranging from simple tural deaths to violent wilful killing, and covering all es from birth to that of a man who claimed 108 years a slight exaggeration into which he had been flattered press attentions.

The proportion of deaths from natural causes was %, roughly two-thirds, a reminder of the vast amount ordinary morbid anatomy passing through the hands the forensic pathologist. Among these 15,000 natural aths were 6267 (41%) in which death took place ddenly, if not instantaneously, on collapse, an unex-cted event precipitating death within a few hours of parently good health. This group I have extracted r study, and I make no apology for concentrating on e principal common disorders rather than the rarer more diverting diseases. I have excluded the hazards birth, such as atelectasis of the lung, and developmental fects which could not properly be included within the bit of disease, for these are problems in other fields.

Cause of Death.—A personal factor must enter into e wording of the cause of death. Where, for instance, nility, hypertension, and coronary occlusion by heroma exist together at death, as is common enough, is reasonable to assume that all three have contributed death. The heading used for such cases has depended the relative contribution assessed for each disease, d in such a matter I have to ask you to trust to my aluation, right or wrong. As age increases, its contri-ution to the decompensation of a heart which has eld hypertension at bay for many years must gradually crease also; it must become increasingly reasonable to y that senility is the cause of such a death. However, his is a human whim, not measurable, which makes roader statistics of this kind unsuitable for mathematical iceties.

The field covered is indicated in the accompanying able. It is a striking feature of the complete table that, mong the common natural causes of sudden death, the ailings of the coronary or cerebral arteries alone account or more than 56%. These, unlike the failings of the orta or of heart valves, rest on the ravages of disease or f what Clifford Allbutt has called the "qualities of issues carried away by the stealthy hours" for which medicine has no known treatment—a sobering thought hich might well stimulate new interest in the athogenesis of arterial sclerosis.

ACUTE ADRENAL INSUFFICIENCY

Ten years ago, in an Erasmus Wilson lecture, I iscussed the pathology of the fatal syndrome of acute drenal insufficiency, finding examples of the diseases ecognised to erase the functioning adrenal rapidly nough to cause death within a few hours (Simpson 937). The most common is undoubtedly bilateral pontaneous hæmorrhage; and, whereas those hæmor-hages which occur after infancy are still recognised as eing largely the result of meningococcal or streptococcal epticæmia (the former in cerebrospinal fever as the Vaterhouse-Friderichsen syndrome), those which arise n the few days or weeks after birth have subsequently een recognised as commonly due to erythroblastosis œtalis and not to the exaggerated hyperæmia of the ndrogenic zone in the postnatal period. Acute caseous tuberculosis and metastatic deposits of malignant growth comprise most of the remainder. Willis (1934) drew attention to the frequency of massive bilateral metastases in the suprarenal glands, especially from growths of the bronchus and breast. Many observers have confirmed his figure of some 9–10% for the frequency of adrenal involvement in all cases of metastatic cancer, and bilateral involvement is as common as unilateral.

RUPTURE OF AORTA WITHOUT ANEURYSM

Aortic rupture is as common without aneurysm as with it—indeed, increasingly more common—and the stimulus of Shennan's monograph (1934) has led to a more critical examination of many ruptures which might at first sight appear to result from the atheroma that is likely to be present (whatever the cause of rupture) after the age of 40.

Hyaline change—fatty atrophy of the medial muscle, mucinoid and hyaline degeneration of the connective tissue, and fragmentation of the elastin—is more common in men (65% males and 35% females in Shennan's original series), and, like all vascular ruptures, is aggravated by hypertension.

The ascending aorta gives way more often than any other part; in about four-fifths of my own 160 cases the burst took place between the aortic valve and the origin of the innominate artery. Hyaline degeneration was responsible for 60% of these.

The reporting of dissecting aneurysm has lagged behind that of rupture without aneurysm simply because though some degree of dissection is almost invariable—as a rule between the media and adventitia—it is usually short, being cut short by rupture into the pericardium. Nevertheless some remarkably long dissections have been recorded, and I have on many occasions traced the

* A lecture delivered to the Royal College of Surgeons on July 29, 1947.

London Medical Exhibition

This exhibition will be held at the Horticultural Hall, Vincent Square, London, S.W.1, from Nov. 17 to 21.

Return to Practice

The Central Medical War Committee announces that Dr. Harold Parsons has resumed civilian practice at 25, Upper Wimpole Street, London, W.1 (Welbeck 9083).

Harveian Society of London

The late Sir Norman Gray Hill, who was killed in Sicily in 1944 while serving with the R.A.M.C., has left half the residue of his estate to this society.

Dr. G. S. W. Organe, consultant anæsthetist to Westminster Hospital, is making a three weeks' lecture tour of Italy on behalf of the British Council.

An expert committee set up by the Interim Commission of the World Health Organisation hopes to publish next year the first draft of an international pharmacopœia (*W.H.O. Chronicle*, 1947, 1, 149).

The first number of a new quarterly, the *Journal of Clinical Pathology*, has appeared this month. Edited for the Association of Clinical Pathologists by Dr. A. Gordon Signy, the journal is published by the British Medical Association. The annual subscription is 25*s*., and single numbers are obtainable for 7*s*. 6*d*.

Appointments

Philps, Seymour, F.R.C.S.: asst. ophthalmic surgeon, St. Bartholomew's Hospital, London.
Roth, Martin, M.D. Lond., M.R.C.P.: senior psychiatrist, Crichton Royal Mental Hospital, Dumfries.
Signy, A. G., M.B. Lond.: pathologist, group laboratory, St. Mary Abbots Hospital, Kensington.
Stuart, R. D., D.Sc., M.D. Aberd., D.P.H.: bacteriologist, Glasgow Royal Infirmary.
Usborne, Mary, M.B. Lond., M.R.C.P., D.C.H.: house-physician, Hospital for Sick Children, Great Ormond Street, London.

The London Hospital:

Ayoub, J. E. M., B.M. Oxfd, F.R.C.S.: asst. ophthalmic surgeon.
Challis, J. H. T., M.R.C.S., D.A.: senior anæsthetist.
Fox, G. P., M.A. Camb., M.R.C.S., D.A.: asst. anæsthetist.
Lister, Arthur, M.B. Camb., F.R.C.S.: senior ophthalmic surgeon.

Births, Marriages, and Deaths

BIRTHS

Chapman.—On Nov. 5, at Chipping Norton, the wife of Dr. John Chapman—a son.
Craig.—On Nov. 1, at York, the wife of Mr. A. J. Craig, F.R.C.S.—a son.
Embleton.—On Nov. 7, at Wokingham, the wife of Dr. J. J. A. Embleton—a son.
Foster-Carter.—On Nov. 7, in London, the wife of Dr. A. F. Foster-Carter—a son.
Hartley.—On Nov. 6, at Loughborough, the wife of Dr. P. L. M. Hartley—a son.
McGowan.—On Nov. 4, at Bristol, the wife of Dr. G. K. McGowan—a daughter.
Moir.—On Nov. 4, at Woking, the wife of Dr. J. H. Moir—a son.
Moore.—On Nov. 3, the wife of Dr. T. S. Moore—a son.
Simmons.—On Nov. 1, at Andover, the wife of Dr. A. B. Simmons—a daughter.
Wickes.—On Nov. 2, at Plaxtol, Kent, the wife of Dr. I. G. Wickes—a daughter.
Wright.—On Nov. 2, the wife of Dr. H. B. Wright—a son.

MARRIAGES

Carter—Grantham.—On Nov. 1, in London, Frederick Stephen Carter, M.B., to Nym Grantham.
Finch—Feldman.—On Nov. 4, in London, Bernard Finch, M.R.C.S., to Patricia Feldman.
Flanagan—Payne.—On Nov. 7, in London, Michael Brendan Flanagan, M.B., to Vera Doreen Payne.
Vincent—Ventor.—On Nov. 8, at Transkei, S. Africa, S. E. Vincent, M.R.C.S., to Joyce Ventor.
Wolfson—Eschelbacher.—On Oct. 29, in London, Leslie Joseph Wolfson, M.B., to Nancy Eschelbacher.

DEATHS

Barnes.—On Nov. 1, at Colyton, Devon, Henry John Barnes, M.R.C.P.E., lieut.-colonel R.A.M.C. retd., aged 89.
Roberts.—On Nov. 7, at Folkestone, Hugh Treharne Llewellyn Roberts, M.A. Camb., L.R.C.P.E., barrister at law, aged 80.
Strickland.—On Nov. 3, at St. Helier, Jersey, Cyril Strickland, M.A., M.D. Camb., aged 66.
White.—On Nov. 9, John Richard White, L.R.C.P.E., aged 89.
Williams.—On Oct. 29, at Killiney, Herbert Armstrong Williams, D.S.O., lieut.-colonel I.M.S. retd., aged 72.

PATHOLOGY OF SUDDEN DEATH [*]

KEITH SIMPSON

M.D. Lond.

CTURER IN FORENSIC MEDICINE, GUY'S HOSPITAL, LONDON

THIS review of the more common pathology of sudden ath is based on an analysis of my own medicolegal se-records of 15,000 necropsies, ranging from simple tural deaths to violent wilful killing, and covering all es from birth to that of a man who claimed 108 years a slight exaggeration into which he had been flattered press attentions.

The proportion of deaths from natural causes was %, roughly two-thirds, a reminder of the vast amount ordinary morbid anatomy passing through the hands the forensic pathologist. Among these 15,000 natural aths were 6267 (41%) in which death took place ddenly, if not instantaneously, on collapse, an unexcted event precipitating death within a few hours of parently good health. This group I have extracted r study, and I make no apology for concentrating on e principal common disorders rather than the rarer more diverting diseases. I have excluded the hazards birth, such as atelectasis of the lung, and developmental fects which could not properly be included within the bit of disease, for these are problems in other fields.

Cause of Death.—A personal factor must enter into e wording of the cause of death. Where, for instance, nility, hypertension, and coronary occlusion by heroma exist together at death, as is common enough, is reasonable to assume that all three have contributed death. The heading used for such cases has depended the relative contribution assessed for each disease, d in such a matter I have to ask you to trust to my aluation, right or wrong. As age increases, its contribution to the decompensation of a heart which has eld hypertension at bay for many years must gradually ncrease also; it must become increasingly reasonable to ay that senility is the cause of such a death. However, his is a human whim, not measurable, which makes roader statistics of this kind unsuitable for mathematical iceties.

The field covered is indicated in the accompanying able. It is a striking feature of the complete table that, among the common natural causes of sudden death, the failings of the coronary or cerebral arteries alone account for more than 56%. These, unlike the failings of the aorta or of heart valves, rest on the ravages of disease or of what Clifford Allbutt has called the "qualities of tissues carried away by the stealthy hours" for which medicine has no known treatment—a sobering thought which might well stimulate new interest in the pathogenesis of arterial sclerosis.

ACUTE ADRENAL INSUFFICIENCY

Ten years ago, in an Erasmus Wilson lecture, I discussed the pathology of the fatal syndrome of acute adrenal insufficiency, finding examples of the diseases recognised to erase the functioning adrenal rapidly enough to cause death within a few hours (Simpson 1937). The most common is undoubtedly bilateral spontaneous hæmorrhage; and, whereas those hæmorrhages which occur after infancy are still recognised as being largely the result of meningococcal or streptococcal septicæmia (the former in cerebrospinal fever as the Waterhouse-Friderichsen syndrome), those which arise in the few days or weeks after birth have subsequently been recognised as commonly due to erythroblastosis fœtalis and not to the exaggerated hyperæmia of the androgenic zone in the postnatal period. Acute caseous tuberculosis and metastatic deposits of malignant growth comprise most of the remainder. Willis (1934) drew attention to the frequency of massive bilateral metastases in the suprarenal glands, especially from growths of the bronchus and breast. Many observers have confirmed his figure of some 9–10% for the frequency of adrenal involvement in all cases of metastatic cancer, and bilateral involvement is as common as unilateral.

RUPTURE OF AORTA WITHOUT ANEURYSM

Aortic rupture is as common without aneurysm as with it—indeed, increasingly more common—and the stimulus of Shennan's monograph (1934) has led to a more critical examination of many ruptures which might at first sight appear to result from the atheroma that is likely to be present (whatever the cause of rupture) after the age of 40.

Hyaline change—fatty atrophy of the medial muscle, mucinoid and hyaline degeneration of the connective tissue, and fragmentation of the elastin—is more common in men (65% males and 35% females in Shennan's original series), and, like all vascular ruptures, is aggravated by hypertension.

The ascending aorta gives way more often than any other part; in about four-fifths of my own 160 cases the burst took place between the aortic valve and the origin of the innominate artery. Hyaline degeneration was responsible for 60% of these.

The reporting of dissecting aneurysm has lagged behind that of rupture without aneurysm simply because though some degree of dissection is almost invariable—as a rule between the media and adventitia—it is usually short, being cut short by rupture into the pericardium. Nevertheless some remarkably long dissections have been recorded, and I have on many occasions traced the

[*] A lecture delivered to the Royal College of Surgeons on July 29, 1947.

course of a rupture which has begun in the aorta and proceeded as far as the upper thighs.

"Twin-bore" malformation of the aorta, with two intima-lined channels, is an interesting condition which illustrates the possibility of healing, and an example of healing of the primary split, included in the present series, has already been reported by Post (1941).

SUBARACHNOID HÆMORRHAGE

Far the commonest natural cause of subarachnoid hæmorrhage is rupture of a developmental aneurysm on the circle of Willis or infrequently on one of its cortical branches. Magee (1943) refers to Symonds's paper of 1924, in which attention was drawn to the frequency of the condition when seriously looked for, and reports the finding of 43 aneurysms in 58 necropsies for subarachnoid hæmorrhage, solitary in all but 5 cases, and on the front half of the circle of Willis as often as on the back half. In my own series 78% had such an origin. Nothing short of stereoscopic dissecting-glasses will provide adequate sight for some of the minute aneurysms. When no dilatation can be found, perfusion is the only sure method of locating the leak.

The use of the word "congenital" for such aneurysms is unfortunate, for they are not present at birth; it is the microscopic anatomy of the cerebral vessels whose development is responsible, and "developmental" is preferable.

Glynn (1940) and Carmichael (1946) have both drawn attention to the important defects of elastin in the internal lamina in the cerebral vessels as distinct from those in the media which occur almost as commonly in many other parts of the body. Of the other factors which contribute to rupture we cannot discount a rise in blood-pressure either in the form of hypertension or from exertion. Some cases in the present series have occurred during moments of maintained tension—e.g., a young garage hand lying under a car, tightening a nut with a spanner, suddenly cried "Oh my head" and collapsed unconscious. He was dead when a doctor arrived four or five minutes later.

A word of caution should be given on the interpretation of these aneurysms later in life. There may be deposits of fat and lipoids in their walls, and some degree of atheroma may, with increasing years, be developing in the circle of Willis. It must not be lightly assumed that saccular aneurysms in such company are of a different pathology; they are likely to be identical in origin. Atheroma of the cerebral vessels leads to a different form of dilatation, not saccular but bulbous, fusiform, and occurring along the course of affected vessels rather than from the stems of their branches.

CORONARY-ARTERY DISEASE

In coronary occlusion lies a cause, perhaps the only natural cause apart from senility, of *instantaneous* death. Coronary occlusion resulting from ostial syphilis, atheroma of the course of the vessel, or thrombosis in addition, rarely rupture, accounted for no less than 26% of the total of sudden deaths; and infarction or rupture, depending on coronary disease, for a further 12% of this series. It is remarkable that this disease should have come into proper recognition only as late as 1910 or 1912, mainly through Herrick and Mackenzie, for it undoubtedly existed in the time of the famous clinico-pathological observers of the 1820–60 period—Addison, Wilks, Bright, Gull, and Hodgkin, to mention only one group at a famous London hospital. In the Gordon museum of Guy's Hospital there were displayed specimens of "myomalacia cordis"—arising from coronary-artery disease no less than from softened infarcts. Rupture was also shown—an event which, except for trauma, I have not seen in nearly 20,000 necropsies unless through an infarct or infarct scar.

Since the sex-frequency and distribution of coronary thrombosis in a series of my own cases has already been reported (Simpson 1939), I shall deal here only with its immediate pathogenesis. Numerous observers, notably Winternitz et al. (1938) and Nelson (1942), have drawn attention to the frequency of subintimal hæmorrhage as a factor in the genesis of thrombosis; the key to the lesion is the vascularisation of the normally avascular intima. When atheroma develops, the new sinusoidal capillaries which develop with the disease are most liable to rupture. Rupture is likely during violent exercise or on direct trauma, and the diffusion of thromboplastic substances is a likely consequence of subintimal hæmorrhage, especially if the diseased intima is ruptured. Any interruption of the smooth flow of blood by obstruction of the lumen is naturally likely to foster the development of thrombi, especially during periods of rest or after collapse from any cause.

As regards trauma causing the development of thrombosis, this conception of the pathogenesis is of great importance. Warburg's (1938) review of 197 cases of non-penetrating injuries of the chest included some in which trauma was associated with coronary thrombosis in a manner which would satisfy searching criticism, though naturally it did not provide exact scientific proof. Stern (1945) describes similar cases whose pathogenesis has been equally critically tested.

ASPHYXIA IN INFANTS

The problem of causation in asphyxial deaths in infancy must be handled with the greatest care; its solution is largely a matter of technique. There is no doubt that bronchitis or bronchiolitis, a common cause of infant death, can develop in as short a time as 12–18 hours (Hubble and Osborn 1941), the child appearing normal when fed, placed in a cot or bed, and dying overnight from the accumulation in sleep of mucopus in the air passages. Thelin (1942), of Zurich, claimed that out of 30 cases he examined because the suddenness of death had precluded certification, or even raised suspicion, he could demonstrate blocking of the lumen by inflammatory secretions in 20. Unfortunately his criteria were not sufficiently critical. During any asphyxiation the lungs became congested and excess mucus, œdema fluid, and even blood will accumulate in the air passages. Only microscopy can detect whether pus also lies in this material. Worse, vomiting may complicate the issue, resulting from asphyxia and adding yet another fluid to that already in the air passages. It is at this point that a serious error commonly arises: the death is attributed to the inhalation of vomit, when in fact the vomit is no more than a reflexion of a state of asphyxia already present. Of Thelin's series of 30 cases 7 (23%) died of suffocation. It is likely that microscopy of the fluid in the air passages would have increased the proportion of cases ascribed to suffocation. In the 233 cases of asphyxia in infants extracted for this survey no less than 93 (40%) were the result of accidental suffocation. The application of more strict criteria virtually doubles the number, excluding as non-inflammatory many air-passage fluids that might incautiously be described from their naked-eye appearance as inflammatory.

Thelin also gave a flicker of life to one now virtually dead bogy, status lymphaticus, when he attributed death to this "state" in 3 of his 30 cases. The status lymphaticus is no more than a status, and if we admit, however unwillingly, the possibility (Campbell 1938), that such subjects may die more readily than others of some trivial cause, that does not excuse the failure to find that cause. We should be no more at liberty to say that a person died of flat-feet or a dwarf stature or some other status.

FOLLOWING early observations by Colebrook and Kenny (1936), Colebrook et al. (1936), and Finklestone-Sayliss et al. (1937) that, in the conditions of in-vitro laboratory experiments, the sulphonamides are not immediately lethal to bacteria, Wolff and Julius (1939) showed that *p*-aminobenzenesulphonamide acts on bacteria only when they are multiplying.

From the growth curves presented by these authors it is apparent that active inhibition by sulphonamide only becomes manifest when the organisms enter the logarithmic phase of growth. Soon after this work appeared, the same conclusion was reached by two of us in these laboratories, as already recorded by O'Meara (1942). Hobby et al. (1942), Hobby and Dawson (1944), and Bigger (1944a and b) subsequently showed that penicillin acts best on rapidly growing bacteria, thus extending the original observation of Fleming (1929) that penicillin is lethal to staphylococci only when they are growing. There is, however, no reason to believe that the sulphonamides and penicillin act on the metabolism of micro-organisms in the same way.

The growth phases of bacteria in a culture may be recorded by counting the number of organisms per c.cm. of culture at intervals during growth and plotting the logarithms of the numbers so found against the corresponding time intervals. A "typical" result is shown in fig. 1; the logarithmic phase of growth appears as a straight line, since during this phase the organisms are increasing numerically in a geometrical progression. But, even at the height of the logarithmic phase not all the organisms in the culture are multiplying at the maximal rate. Thus Wilson (1922) has shown that some of them are dying, and Hirsch (1933) found that multiplication took place in spurts. It follows that some are out of step with the majority, either not having yet reached the logarithmic phase or having passed beyond it.

BACTERIA IN LOGARITHMIC PHASE OF GROWTH ARE SUSCEPTIBLE TO SULPHONAMIDES

That it is bacteria in the logarithmic phase of growth which are susceptible to sulphonamides is shown conclusively with logarithmic-phase cultures. These are prepared by subculturing the organisms, when they are at the height of the logarithmic phase of growth in an ordinary culture, into media so adjusted that growth in the subculture continues in the logarithmic phase without interruption. In these conditions the sulphonamides are immediately lethal to bacteria. A logarithmic-phase inoculum is introduced into a control medium and into the same medium with a suitable concentration of added sulphonamide derivative, and bacterial counts are made immediately and at intervals. Growth continues in the control in the logarithmic phase, whereas in the presence of the sulphonamide derivative the culture becomes sterile within an hour. We have used *Bact. coli* with urine as the culture medium and *Strep. pyogenes* with meat-extract-peptone broth to which were added 0·2% glucose and 0·1% sodium bicarbonate. Both the urine and the broth were sterilised by filtration. In all experiments the media were warmed to incubator temperature before inoculation. Bacterial counts were made by the usual cultural methods immediately after inoculation of the media, and at hourly intervals thereafter, for 8 hours as a rule, and finally at 24 hours.

In fig. 2 growth of *Bact. coli* in urine and in urine containing sulphapyridine 40 mg. per 100 c.cm. are compared. The inoculum is from an ordinary 24-hour culture which has passed the logarithmic phase. It will be seen that a 30-fold increase in numbers takes place in the presence of sulphapyridine before the compound begins to act. Sterility is only achieved somewhere between 8 and 24 hours after inoculation.

In fig. 3 the results of using a comparable inoculum of *Bact. coli* in the logarithmic phase of growth are shown. The growth of the control continues geometrically, whereas in the urine containing sulphapyridine sterility is established within an hour.

The corresponding results for *Strep. pyogenes* in the appropriate medium and in the same medium with sulphapyridine 20 mg. per 100 c.cm. added are shown in figs. 4 and 5.

To obtain results as perfect as those shown in figs. 3 and 5 it is necessary to determine exactly, by trial, the period of incubation which brings the preliminary culture to the height of the logarithmic phase. If the inoculum is withdrawn too early or too late, the number of organisms which have not reached the logarithmic phase, or which have passed it, is too great to permit a perfect result. It is also necessary to use a small inoculum of not more than about 100 organisms per c.cm.

Fig. 6 shows the result likely to be obtained if the *inoculum is not fully in the logarithmic phase of growth.* The same type of result is obtained by using too large an inoculum, even though it be taken from the height of the logarithmic phase.

IN SEPTICÆMIA BACTERIA ARE IN THE LOGARITHMIC PHASE

The technique of obtaining logarithmic growth *from* the moment of inoculation may be used to determine whether bacteria causing infection are growing in the logarithmic phase or not. Experimental pneumococcal septicæmia in the mouse lends itself to such investigation, since the organisms are present in the blood-stream of the animal in large numbers shortly before death. Blood is taken from the heart of such animals and is inoculated into the medium used for growing streptococci, or into a similar medium, with 5% added rabbit serum, the medium being warmed to 37°C before inoculation. Bacterial counts are done immediately and at intervals. It is difficult to judge the optimal period for withdrawal of the blood, but most successful cultures start to proliferate immediately without an initial stationary period. They are often not quite in the logarithmic phase though very near it. The results may be interpreted as showing that the great majority of the organisms are in the logarithmic phase, and allowance has to be made for the imperfections inevitable in an experiment of this kind.

NATURE OF THE CHANGES DURING LOGARITHMIC PHASE OF GROWTH

Bacteria in the logarithmic phase of growth are causing extremely rapid chemical and physical changes in their internal and external environment. They are engaged in fission of those materials in the medium most suited to providing both energy for growth and essential growth requirements. They are assimilating the products of fission, many of which are chemically highly reactive. The physical and chemical changes in bacterial cultures most nearly concerned with the speed of bacterial growth are those related to the sources from which energy for growth is derived. Most pathogenic bacteria utilise the fermentable substances in the media, particularly fermentable carbohydrate such as glucose, if it is present even in traces, as their chief source of energy in the early stages of growth. At the same time there is a fall in pH due to the production of acid, mainly lactic acid, from the sugar. The oxidation-reduction potential of the medium also falls, at first slowly but during the logarithmic phase of growth very rapidly. Hewitt (1936), among others, has studied the redox potentials of cultures of many pathogens. In general their behaviour is similar to that described though differing in detail and degree.

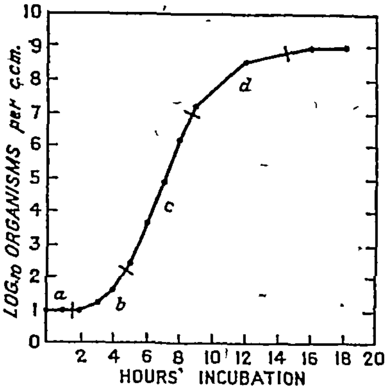

Fig. 1—A typical curve of bacterial growth: (a) initial stationary period; (b) lag phase; (c) logarithmic phase; (d) phase of negative growth acceleration.

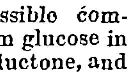
As has been previously noted (O'Meara et al. 1944), the rapid development of reducing conditions in the medium must be due to the formation of a substance of great reducing intensity. A sulphydryl compound of the general formula R—SH suggests itself as an obvious possibility, but is ruled out by the fact that not all bacterial cultures which provide the reduction give a positive nitroprusside reaction, as they would be expected to do if sulphydryl were responsible. Another type of compound must therefore be sought; and, in view of its probable formation from carbohydrate, a dienol compound containing the group



$$\begin{array}{cc} -\mathrm{C} = & \mathrm{C}- \\ | & | \\ \mathrm{OH} & \mathrm{OH} \end{array}$$

suggests itself for consideration. The possible compounds of this type likely to be derived from glucose in bacterial cultures are ascorbic acid, glucoreductone, and dihydroxyacetone.

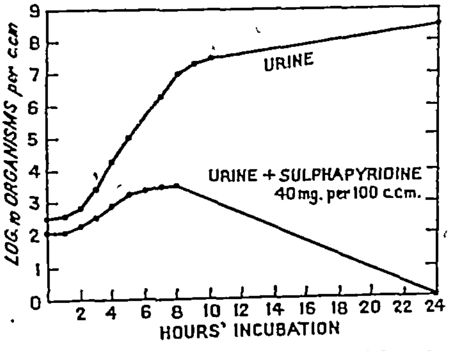


Fig. 2—Growth of *Bact. coli* in urine and in urine containing sulphapyridine. Ordinary inoculum.

PRODUCTION OF A DIENOL COMPOUND BY BACTERIA DURING GROWTH

The production of a dienol compound by the commo pathogens during growth on ordinary laboratory medi is readily shown by the test described by Fearon Kawerau (1943). The organisms are inoculated heavil on to nutrient agar slopes and tested at intervals by wasl ing the growth to the bottom of the slope with abo 1 c.cm. of a saturated aqueous *o*-dinitrobenzene solutio and then adding a drop of 20% caustic-soda Table I shows that all the organisms tested gave a positiv result for the production of a dienol compound, shown by the development of a purple colour, strongest results being obtained early in growth wi such organisms as *Bact. coli*, *Bact. aerogenes*, and *Stap aureus*, which grow vigorously in these circumstances.

Production of ascorbic acid in bacterial cultures h been shown by Büsing and Peters (1940), using *Chrom bact. prodigiosum*. The dienol compound produced b the pathogens does not, however, appear to be ascorb *acid, since it repeatedly failed to give the dihydr* ascorbic-acid test of Fearon and Kawerau (1943), whi is specific for ascorbic acid. The compound produce by bacteria is therefore either glucoreductone or dih droxyacetone. Of these, the former is the more probabl When media of the type used in these experiments a heated for a few minutes in boiling water they w reduce methylene-blue. The pathogens inoculated in media so heated start to grow more readily than unheated media. Hence it is probable that the reduci substance available f immediat utilisation b the orga nisms. It ha been show by O'Mear (1937) th the *concen* tration of th meat extrac prepare freshly fro meat decide the rate which reduc tion will place when the media are heated. There is good reaso to believe that it is the free sugar content of the extrac which determines its reducing power. Moreover, th media are alkaline, and it has been shown by von Eul and Klussmann (1933) and von Euler and Martius (1933 that glucoreductone is readily formed when a such as glucose is heated with alkali. The media use in the experiments recorded in table I gave a *o*-dinitrobenzene test after they had been heated some minutes in boiling water. *Taking all these fac* into consideration it is highly probable that th dienol compound formed by bacteria during growth glucoreductone.

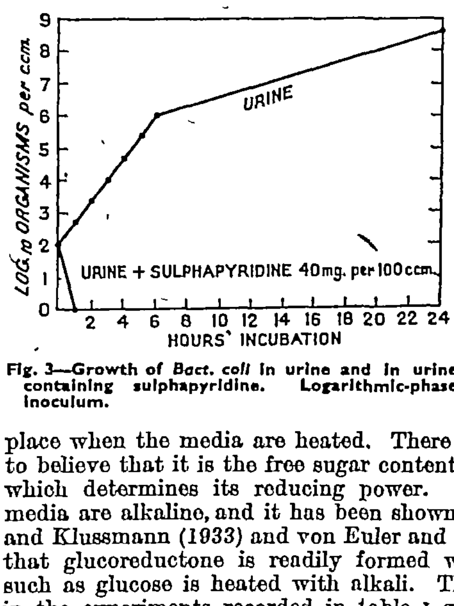

Fig. 3—Growth of *Bact. coli* in urine and in urine containing sulphapyridine. Logarithmic-phase inoculum.

CHEMICAL INTERACTIONS OF *p*-AMINOBENZOIC ACID AN SULPHONAMIDE DERIVATIVES WITH GLUCOREDUCTONE

Highly reactive aldehydic compounds, such as gluco reductone, $CH_2OH.CO.CHO$, form condensation pro very readily with *p*-aminobenzene derivatives. Gluc reductone may be prepared in solution by methods such as the following modified from von Euler and Marti (1933):

> 20 c.cm. of 10% glucose solution is heated with 1 c.cm. of 20% caustic soda at 77°C for 10 min. The solution turns brown. After heating, 1 c.cm. of glacial acetic acid is added and the mixture is cooled.

This solution may be used to prepare condensation products of reductone and the *p*-aminobenzene derivatives. Thus, by saturating the acid solution with *p*-aminobenzoic acid a yellow colour is produced, and a heap of yellow crystals soon begins to be deposited on the unaltered *p*-aminobenzoic acid at the bottom of the tube. The yellow crystals are repeatedly washed with acidulated water until free from *p*-aminobenzoic acid. These crystals are a compound of *p*-aminobenzoic acid and glucoreductone. They are insoluble in water, in which they give a fluorescent suspension, but go into solution with ease on the addition of a trace of alkali, to give a yellow solution in which the compound rapidly undergoes hydrolysis, even at room temperature, to give a colourless solution. After hydrolysis a positive dinitrobenzene test indicating the presence of reductone and a positive Ehrlich reaction indicating the presence of *p*-aminobenzoic acid are given by the solution.

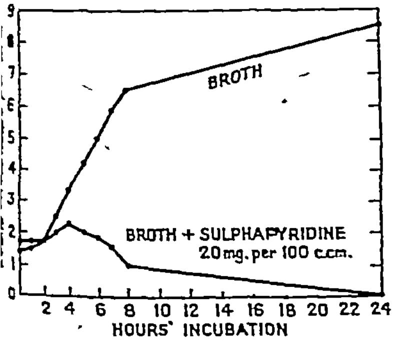

Fig. 4—Growth of *Strep. pyogenes* in broth and in broth containing sulphapyridine. Ordinary inoculum.

The sulphapyridine and sulphathiazole derivatives of reductone have also been isolated. The sulphanilamide reductone compound, owing to its solubility, has not been obtained free from sulphanilamide. Both ascorbic acid and dihydroxyacetone form yellow solutions with *p*-aminobenzoic acid and the sulphonamides. The condensation reactions are slow, and the products of condensation have not been isolated. In referring further to the compounds formed with reductone we shall use the contractions R-P.A.B. for that derived from *p*-aminobenzoic acid, and R-S.A., R-S.P., and R-S.T. for those derived from sulphanilamide, sulphapyridine, and sulphathiazole respectively. Some of their properties are summarised in table II.

The chemical characteristics of these compounds will be the subject of further investigation, but certain properties emerge from this study which correlate well with the observed biological behaviour of *p*-aminobenzoic acid and the sulphonamides (Stamp 1939, Green 1940, Woods 1940, Fildes 1940, Rubbo and Gillespie 1940, 1942).

The extreme ease with which reductone condenses with *p*-aminobenzoic acid to form R-P.A.B. and the ease with which this compound dissolves and undergoes hydrolysis within the biological range of pH suggest that the function of *p*-aminobenzoic acid in bacterial metabolism is to stabilise and temporarily to conserve for use of the cell the extremely active chemical substance glucoreductone formed by breakdown of carbohydrate. Glucoreductone is likely to be an essential source of energy for growth and of carbon for assimilation. It is, at the same time, likely to prove toxic to the cell, by reason of its chemical reactivity, if it is allowed to accumulate in the environment. Moreover, it will be lost by spontaneous oxidation unless stabilised. The oxidation takes place rapidly and is catalysed by copper, which was shown by O'Meara (1937) to have a deleterious effect on the reducing power of bacteriological media and on the maintenance of a low potential by bacteria.

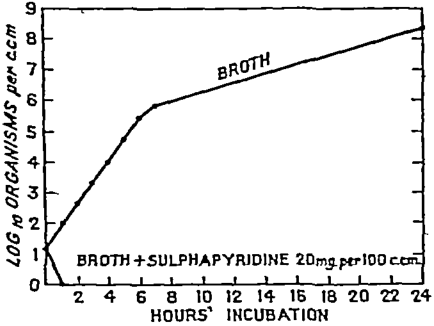

Fig. 5—Growth of *Strep. pyogenes* in broth and in broth containing sulphapyridine. Logarithmic-phase inoculum.

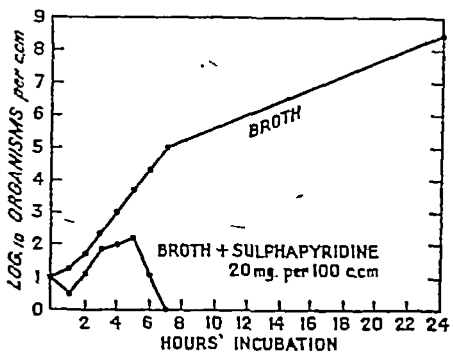

Fig. 6—Growth of *Strep. pyogenes* in broth and in broth containing sulphapyridine. Inoculum not quite in logarithmic phase.

In normal metabolism, therefore, bacteria utilising carbohydrate as a source of energy for growth probably form R-P.A.B. with the reductone which they produce. They then utilise the reductone as required, setting it free from R-P.A.B. Anything which interferes with the production of R-P.A.B. or destroys reductone or diverts it from normal utilisation by the bacteria will disorganise normal metabolism. The production and assimilation of reductone may be interfered with in several ways. By the addition to cultures of substances of similar chemical structure to *p*-aminobenzoic acid with an amino group in the para position, such as the sulphonamides, it is to be expected that reductone will be diverted to form condensation products unable to be used by the bacterial cell. Some compounds will be more active than others, and their activity may be expected to be related to the readiness with which they form derivatives with reductone and the firmness of their combination with reductone or their tendency to combine with reductone in a way different from that which leads to the formation of R-P.A.B. The three sulphonamide compounds which we have studied are, in ascending order of antibacterial activity, sulphanilamide, sulphapyridine, and sulphathiazole. With reductone sulphanilamide forms the least stable and most readily hydrolysable compound. The compound formed with sulphathiazole is most stable, the sulphapyridine compound being more stable than that with sulphanilamide and slightly less than that with sulphathiazole. These findings are in agreement with the antibacterial activity of the substances.

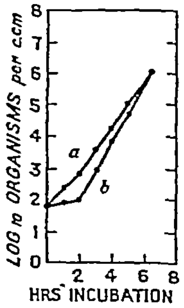

Fig. 7—Growth of pneumococcus: (*a*) inoculum from mouse septicæmia; (*b*) inoculum from ordinary 18-hr. culture.

It also follows that *p*-aminobenzoic acid should be able to inhibit the action of the sulphonamide derivatives. Its power of inhibition should be greatest with sulphanilamide, less with sulphapyridine, and least with sulphathiazole, in view of the stability of their reductone derivatives. This is also in accordance with the observed experimental facts of the inhibitory action of *p*-aminobenzoic acid on the sulphonamide derivatives (Medical Research Council 1945).

Another way in which the utilisation of reductone could be interfered with is by oxidation. In this connexion attention may be drawn to the finding of McLeod this view it is shown that growing bacteria assimilate *p*-aminobenzoic acid and sulphonamides added to their environment.

This view of the mode of intracellular action of the sulphonamide derivatives is compatible both with their known relationship to *p*-aminobenzoic acid and the observations which show that their activity is enhanced by oxygen.

Our thanks are due to Prof. W. R. Fearon and Dr. E. Kawerau for helpful suggestions in the search for the dienol derivative. One of us (H. G. N.) was in receipt of a grant from the Sarah Purser Medical Research Fund.

STAPHYLOCOCCAL PNEUMONIA IN CHILDHOOD

PATHOLOGICAL CONSIDERATIONS

K. J. GUTHRIE
M.D. Glasg., D.P.H.
ASSISTANT PATHOLOGIST, ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

GEORGE L. MONTGOMERY
T.D., M.D. Glasg., Ph.D. St. And., F.R.F.P.S.
GARDINER LECTURER IN PATHOLOGY OF DISEASES OF INFANCY AND CHILDHOOD, UNIVERSITY OF GLASGOW; PATHOLOGIST, ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

PRIMARY staphylococcal pneumonia ranks among the gravest forms of staphylococcal infection in childhood. It occurs in epidemic and sporadic forms; but, though both forms appear to have been recognised more often in recent years, neither is common.

We have observed 55 necropsy cases of staphylococcal pneumonia in children, all under the age of 7 years, two-thirds of them being less than 6 months old, at the Royal Hospital for Sick Children, Glasgow. In addition one of us (K. J. G.) investigated in a maternity nursery an outbreak of staphylococcal infection which included 16 cases of pneumonia. Together these cases form a larger series than any of which we have knowledge, and for this reason and because penicillin is now generally available it seems timely to direct attention to the pathology of staphylococcal pneumonia.

Epidemic Form.—Epidemic staphylococcal pneumonia is often associated with an outbreak of virus influenza, which predisposes to secondary invasion by pyogenic organisms.

Fraenkel (1904) was apparently the first to isolate staphylococcus in pure culture from the lung and pleura o pneumonia patient. Habbe (1929) found staphylococcus a secondary invader more often in influenzal than in oth types of pneumonia. Chickering and Park (1919), Tyt et al. (1919), and Patrick (1919) record staphylococcal pne monia after clinical influenza in young soldiers. Wollenm and Finland (1943) described necropsy findings in 8 ol people.

In young infants staphylococcal pneumonia may a be met with in epidemic form apart from influenza other virus infection, as in the nursery outbreak report by Smith (1935). Cohen (1938) remarks on "the wa like incidence of staphylococcus pulmonary infecti and its propensity for infants in particular."

Sporadic Form.—Staphylococcal primary pneumo in its sporadic form appears to be predominantly children's disease, and according to Macgregor (Scott Scientific Advisory Committee 1947) it is commoner the neonatal period than at any other time of life.

Lyon (1922), on bacteriological examination of sputu lung puncture, blood, and empyema fluid during life, fo *Staph. aureus* to be the causal agent in 3 out of 31 case bronchopneumonia in infants and children. From necro material Menten et al. (1932) isolated *Staph. aureus* in of 131 cases of pneumonia in children. Out of 6 cases Reim (1933) had 1 in an infant, and another single case is quo by Cass (1940) in a paper on staphylococcal infections the newborn. Macgregor (1936) described 10 sporadic ca of staphylococcal pneumonia in children, and Kanof et (1939) had 37 cases in children, but of these only 25 w primary. Gaspar (1941) examined post mortem 144 ca of pneumonia, in 38 of which staphylococcus was the p dominant or only organism. Of these, 20 were under one y of age and 8 between the second and tenth years. Clem and Weens (1942) had 6 examples in early infancy.

Staphylococcal empyema, since it often complicat staphylococcal pneumonia, is also essentially a lesion the younger age-groups.

Kanof et al. (1939) found it in their infantile cases often that they considered it to be an integral part rat than a complication of the disease. Cohen (1938) attribu this to the smaller bulk of lung tissue between the ple and the bronchi in children's lungs than is the case in adul In their series of 33 children, Ladd and Swan (1943) show that the incidence of staphylococcal empyema was great in the first year and indeed in the first three months of li They regarded age as the most important factor in progno with a sharp dividing line at the age of four months; 12 patients below this age 8 died, whereas there was only death in patients older than four months.

HOSPITAL CASES

Pathology

The 55 hospital cases consisted of 45 in which pulmona consolidation was the outstanding feature and 10 which the pneumonia was associated with suppurati bronchitis and bronchiolitis; in 2 it was accompani by acute bronchiectasis, and in 3 by pulmonary absce

The consolidation varied from a dark red hæmorrhag pneumonia, simulating lobar pneumonia both in appea ance and distribution, to a diffuse grey pneumonia wi suppurative softening which sometimes amounted a localised abscess. The simple hæmorrhagic lobar-li pneumonia was present in 10 cases, and in all of the the duration of illness had not exceeded two day When the illness had lasted longer it was common find early suppurative change in a lobe which ha obviously been wholly hæmorrhagic at the onset, whi red consolidation, clearly more recent, bordered th suppurative areas or affected adjacent parts of oth lobes. Fibrinous pleurisy was present in 16, and emp ema in 26, of our cases. As a rule the empyema w unilateral and had produced partial collapse of lung pyopneumothorax was present only in 1 case. Thoug the empyema pus was usually thick and yellow, som it was watery and brownish-red. In contra- on to its frequency in pyæmic staphylococcal nias, purulent pericarditis occurred only twice the series; no metastatic abscesses were found in organs.

roscopically the appearance of the lungs varied in ce with the macroscopic findings. Where the n on inspection was mainly hæmorrhagic con- on, microscopical examination showed groups of packed with red blood-cells as in an infarction. consolidation was not, however, so confluent as the eye appearance had suggested, and the alveoli the margins of the hæmorrhagic areas were often with eosinophilic fibrin-free œdema fluid containing alveolar phagocytes and small groups of gram- e cocci. Nor was this spreading œdema limited the hæmorrhagic pneumonias; it could be seen es at the periphery of well-established areas of tion or in otherwise healthy contiguous lung.

ter a virulent staphylococcal infection had lasted days, the microscopical appearances were com- There were numerous abscesses, some in relation nchi and often with well-defined pyogenic mem- and clumps of staphylococci. These suppurative were separated by consolidated hæmorrhagic or tous lung. Where pus existed in the smaller air els, there was usually a well-established bronchitis bronchiolitis, with extensive cellular infiltration and ction of the bronchiolar walls, amounting in some to acute bronchiectasis. Nevertheless the bronchial often remained intact even to the ciliated epithelium, te pus in the lumen.

ology

ph. aureus was isolated at necropsy from all cases the R.H.S.C. series; in a few instances the organism also been obtained during life from pleural pus throat and nasal swabs. The positive necropsy res totalled 119. Single specimens were examined 24 cases, and two, three, and four specimens from remainder. Pus—e.g., from pleura, lung abscess, bronchus—was cultured; where there was no obvious cultures were made by puncturing consolidated of lung after searing the pleural surface. A few swabs were cultured post mortem and these mostly ded *Staph. aureus*. This organism was isolated from cases of pericarditis.

rom the great majority of specimens cultured the hylococcus was pure. Sometimes, however, material ained by lung puncture or from bronchial exudate wed a combined staphylococcal and coliform flora ect films gave valuable information about the nature the infection), and for this reason we often used ssium tellurite in a dilution of 1/100,000 to suppress form contaminants (Medical Research Council 1940). Most of the strains of *Staph. aureus* from sporadic epidemic cases were deeply pigmented and non- olytic on fresh blood-agar plates. In earlier cases ulase tests were not performed, but with these eptions all other strains were strongly coagulase- tive; those tested for penicillin sensitivity were ally inhibited to about the same degree as the Oxford dard staphylococcus. Specific phages for typing e not available to us.

SICK NURSERY OUTBREAK

One of us (K. J. G.) had personal experience of a small demic of staphylococcal infection in the sick nursery a maternity hospital, where a series of neonatal ths, chiefly among small premature infants, occurred the winter of 1943–44 while mild clinical influenza present among the mothers and the nurses. The ants affected were as a rule healthy at birth. After days of normal progress they suddenly collapsed, quickly became dehydrated and cyanosed, and died within 24–48 hours, without localising symptoms.

Bacteriological and Necropsy Findings

Material for bacteriological examination was obtained before death from some infants and from the whole 44 coming to necropsy. Since the clinical findings gave no clue to the nature of the disease, and since infections in premature infants are often atypical, a fairly comprehensive bacteriological investigation was necessary. Throat and nasal swabs and lung punctures were cultured on routine media to exclude the common respiratory pathogens, and mice were inoculated for pneumococci. Rectal swabs were examined, but no intestinal pathogen was isolated. Blood and spleen cultures were taken to exclude septicæmia. Pneumococci and hæmolytic streptococci were rarely recovered, and *Staph. aureus* was the only pathogen which recurred constantly throughout the investigation, having been isolated from 27 of 31 throat swabs, 40 of 54 lung punctures, and from almost half the 50 combined blood and spleen cultures.

Prof. C. H. Browning kindly performed mouse-virulence tests on several strains from the nursery outbreak; these were only moderately lethal to mice.

At necropsy lesions were confined to the respiratory tract. Of the 44 babies examined, 24 showed only slight hypostatic congestion of the lungs, sometimes with a few petechial hæmorrhages or patchy atelectasis. Pneumonia was present in 16, being localised in 4 and diffuse in 12. Of the 12 diffuse pneumonias 6 were hæmorrhagic and 1 had also multiple abscesses; the remaining 5 were ordinary non-suppurative bronchopneumonias. Multiple small lung abscesses without obvious pneumonic consolidation were present in the other 4 cases.

A more or less heavy growth of *Staph. aureus* was obtained from 10 of the 12 diffusely consolidated lungs, and from 3 of the cases with lung abscesses only. In some instances *Staph. aureus* was isolated also from other sources, such as throat swabs or blood or spleen cultures. No case showed empyema or fibrinous pleurisy; the bronchial tree throughout the series was free from inflammatory change and exudate.

Microscopically the pneumonic lungs showed areas of hæmorrhagic and of suppurative pneumonia with purulent bronchitis and bronchiolitis. Though there was considerable confluence of the pneumonic areas, the condition had clearly begun as bronchopneumonia. Acute vesicular emphysema separated the consolidated portions of lung. A feature of these neonatal lungs was the presence in the alveoli of large clumps of gram-positive cocci. Many of the infected alveoli had merely intense capillary congestion without inflammatory cellular infiltration or exudate, but suppuration with masses of cocci was the rule in the bronchi.

Source of Infection

It is impossible to say whether the staphylococcus alone was responsible for this epidemic, or whether it was associated with a mild type of virus influenza. An attempt was made, however, to trace the source of the staphylococci. No increased antecedent or concurrent incidence of staphylococcal infection, such as mastitis, was reported among the mothers, and the normal infants were free from pemphigus and other staphylococcal manifestations. Attention was then directed to the nurses, from whom multiple throat and nasal swabs were cultured. Of a total of 75 swabs 12 were positive for staphylococci, a figure which compares favourably with others reported in mass investigations of throat and nasal swabs in adults. Thus Gillespie et al. (1939) recorded a nasal carrier-rate of 33·4% in 159 students, and Miles et al. (1944) found relatively large numbers of staphylococci in the nares of 40–50% of over 1000 normal adults.

To exclude milk as a vehicle of infection, prepared feeds were examined and they were found to be sterile. An exogenous source of infection thus appeared improbable, and the staphylococcal lung lesions were evidently endogenous, due to a downward spread of organisms present in the upper respiratory tract. Most of these infants were nasal carriers of staphylococci, and it is well-known that feeble premature children are ill adapted to combat such infection.

DISCUSSION

In this children's hospital the bacteriology of respiratory disease has always received considerable attention, and we have found that the incidence of staphylococcal pneumonia has increased within recent years. This view is endorsed by Cohen in America. Similarly, Bracken (1941) noted a sharp rise in the percentage of staphylococcal pneumonia in adults in the last of the five-year periods he investigated in Pittsburgh. In Edinburgh also, Macgregor (1936), who recorded 10 cases of staphylococcal pneumonia in children within a year, remarked that the occurrence of so many sporadic cases in so short a time possibly indicated a phase of increased staphylococcal virulence.

Since small children swallow sputum, it is not available for bacteriological examination, and the incidence of staphylococcal pneumonia during life is difficult to assess. For this reason most of the published records are based on necropsy findings or on the culture of empyema fluid.

On comparing the necropsy records of this hospital in 1926–35 with those of the following decade, it is noted that, of 2300 consecutive necropsies in 1926–35, primary pulmonary staphylococcal infection was diagnosed in 3 cases only, whereas of 2877 consecutive necropsies in 1936–45, it was diagnosed in 55 cases. In both decades the proportion of necropsies to deaths has been more or less uniform, and thus there is a factual basis for the view that staphylococcal pneumonia has recently increased in this hospital.

Analysis of the bacteriologically investigated empyemata, of which we have complete records since 1928, yields supporting evidence. Care has been taken to exclude empyemata arising in the course of a staphylococcal pyæmia. Blacklock and Guthrie (1933) found that, of 46 fatal cases in which empyema complicated the pneumonia, 41 were pneumococcal, 4 streptococcal, and only 1 staphylococcal. Of 219 empyemata in 1931–45, all occurring in the course of respiratory infections, 10·5% were due to *Staph. aureus* alone. Like other workers (Riley 1944), we have noted in this hospital that, since the routine use of sulphonamides in pneumonia, the number of empyemata due to sulphonamide-sensitive organisms has diminished; on the other hand, there has been an increase, both relative and absolute, in staphylococcal empyemata.

We wish to emphasise the rapidly fatal character of the disease, whether sporadic or epidemic, in young children. Among our hospital cases the whole duration of illness in one child of 15 months was thirty hours; three children of 4 weeks, 1 year, and 4 years died thirty-six hours after onset; and six had an illness lasting not longer than two days. These children had apparently been previously healthy, and it was usually severe dyspnœa which first attracted attention, or sometimes the onset was accompanied by rigor, cough, and vomiting. In the nursery epidemic, affecting weakly and premature infants, sudden collapse was the most arresting feature, and death often occurred too quickly for localising signs to develop. The report on neonatal deaths due to infection (Scottish Scientific Advisory Committee 1947) emphasises that in maternity hospitals infection among infants, especially in the premature group, may appear and run its course without being recognised either as a cause of sickness or deat as an unwitting source of spread, because of highly elusive signs and symptoms.

Some writers regard the child's age as the fa which determines the type of lung lesion. Gaspar (1 in his series of 28 cases (20 of them under a year found that the staphylococcal pneumonias seen in first ten days of life appeared as lobular or lobar solidations, dark red and hæmorrhagic on section. similarity between early staphylococcal pneumonia pneumococcal pneumonia in the stage of red hepatisa is emphasised also by Smith (1935) and Genni (1943). Ladd and Swan (1943) contrasted the exud hæmorrhagic reaction frequent in infancy with staphylococcal abscesses which they saw more ofte older children. Analysis of our material has sh that the pulmonary lesion was related not to the of the child so much as to the duration of the ill since infants only a few days old sometimes live week or more after the onset and came to necr with suppurative lung lesions. Hæmorrhagic p monia, then, was in our experience the character finding in staphylococcal pulmonary infections of s duration, and it was often associated with sprea alveolar œdema.

Hæmorrhagic pneumonia with œdema is likewise earliest acute pulmonary lesion of human virus influe and it is also an experimental finding. McCordock Muckenfuss (1933) found, in rabbits given intratrac injections of vaccine virus, that the earliest gross ch was an exudative lesion consisting of œdema coagulated albuminous fluid and flakes of fibrin in alveoli. Alveolar hæmorrhage with focal nec developed rapidly in the most acute cases where st virus was used. True lobar and lobular pneum could not be induced by injection of virus alone, were produced together with bronchial and peribronc abscesses when pyogenic cocci were introduced the virus. This suppurative process developed slowly and thus corresponded to the lung lesions w we saw in staphylococcal pneumonia of longer durat

The bacteriological findings support the view acute staphylococcal pneumonia in children is a bronchogenic infection, either endogenous or exogen probably the former as a rule, though only in 3 of hospital series was there a definite history of an a cedent nasal discharge. This is a surprisingly s number, but in the nursery epidemic *Staph. aureus* isolated on direct plating from nasopharyngeal sw of about 90% of sick babies, whereas in a control se of 50 healthy premature infants nearly 65% w positive. Smith (1935) also found a high nasal stap lococcal carrier-rate among infants of a matern hospital in which a staphylococcal epidemic had brol out. Cruickshank (1946) refers to the high incide (80–100%) of nasal carriers of *Staph. aureus* in the f few weeks of life, and thinks that the nose is the reserv from which endogenous infection spreads, since " newborn infant is ill adapted to cope with bacte invasion." In 6 of our cases, however, the staphy coccal pneumonia appeared to be a hospital (exogeno infection. These children were all infants under months of age, 5 having been admitted to hospi because of failure to thrive or of continuous vomiti and 1 because of coliform pyuria. On admission evidence of respiratory disease could be detected, a the infants seemed to improve for some days, when sudden rise in temperature heralded the onset of pn monia. Death took place within a few days, a necropsy revealed extensive pulmonary consolidation.

In view of the pronounced sensitivity to penicil of most strains of *Staph. aureus*, it appears that in su urgent cases penicillin would offer the best chance controlling the infection. Our observations on t pathology and bacteriology of staphylococcal pneumonia in children show that even in the earliest stages there is an extensive loss of aerating lung surface, so that penicillin, if it is to be effective, must be given early and in adequate dosage.

Diagnosis, particularly in the sporadic cases, is difficult. Considerable experience has convinced us of the uncertainty of lung puncture and the unreliability of throat swabs in the bacteriological diagnosis of pneumonia in childhood; and to await the results of bacteriological examination is to lose valuable time. In our opinion there is a prima-facie case for the exhibition of penicillin, with or without sulphonamides, empirically in all grave pneumonias in childhood, or when sudden dyspnœa or rise in temperature complicates a postnasal or upper respiratory infection in infants. Diagnostic difficulties are less in the epidemic form of the disease—for example, in maternity nurseries—and under these conditions penicillin may be used prophylactically.

The feasibility of administering penicillin by mouth has simplified its use in childhood. Buchanan (1946), working in this hospital, found that 4000 units of penicillin per lb. of expected body-weight daily, given in feeds to children under six months of age, yielded blood-penicillin levels comparable with those obtained with three-hourly injections of similar amounts. There is no objection to increasing this dose, and the 10,000-unit tablets manufactured by Burroughs Wellcome & Co. dissolve readily in feeds and are convenient in use. Further work has shown that these results can be obtained with certainty only in premature children and in infants in the first month of life, and though up to the age of six months most children absorb penicillin by mouth there is a proportion, increasing with age, which do not. Therefore in children over the age of a month it is prudent in grave illness to give three-hourly injections of penicillin in a dosage of not less than 4000 or 5000 units per lb. of body-weight daily. Older children tolerate the continuous intramuscular drip reasonably well.

The rapid spread of pulmonary œdema in acute cases suggests that oxygen should not be omitted from the therapy, and the delay in establishing bacteriological diagnosis is an argument in favour of combining penicillin with sulphonamides. A further reason for this combined treatment is the tendency for penicillin-insensitive organisms to appear during the course of penicillin therapy. Coliform replacement was known to occur in war wounds infected originally with staphylococci (Thomson 1944), and we have met with a pure coliform flora at necropsy, both in films and in cultures from multiple specimens, in bacteriologically proved staphylococcal pneumonias treated with penicillin.

A typical alteration in flora was seen in a male infant aged 4 weeks who developed bronchopneumonia with much cyanosis and dyspnœa and from whose sputum *Staph. aureus* was isolated on Feb. 28, 1946.

Penicillin by mouth, in a dosage of 9000 units six times a day, was begun on that day and was continued for ten days without improvement. Sulphadiazine was then given in an initial dose of 0·5 g. followed by 0·25 g. four-hourly. On March 11 thick muco-pus aspirated from the pharynx gave a pure coliform growth, insensitive to penicillin.

The child died that night, and at necropsy both lungs showed diffuse consolidation, with early suppurative softening and pus-filled bronchioles. A film of lung-puncture material showed coliform bacilli, and culture of this and of bronchial pus produced a pure coliform growth of ordinary fæcal type.

Such replacement has been recorded by Southwell (1946) during the treatment of bronchiectasis with inhaled penicillin, where after the elimination of penicillin-sensitive organisms from the sputum a luxuriant growth of coliform bacilli developed. It must be noted, however, that pneumonia in the neonatal period may be due solely to coliform bacilli (Macgregor 1947), which is another reason for combining penicillin with sulphonamides.

SUMMARY

Staphylococcal pneumonia appears to be becoming more common.

A grave disease with a high mortality, particularly in infants, this infection occurs both in sporadic and epidemic forms, and in epidemics is often secondary to virus infection, particularly influenza.

Pathological changes in children vary according to the duration of the disease. The earliest stage is a hæmorrhagic exudative reaction simulating the red hepatisation of lobar pneumonia, and this is particularly likely to be found in infants.

Premature babies have a poor resistance to the staphylococcus, and in lung infection death may take place with minimal pulmonary reaction, though the lungs contain abundant cocci.

The early exhibition of penicillin in adequate dosage combined with sulphonamides is recommended.

We wish to thank the clinical staff of the Royal Hospital for Sick Children, Glasgow, and of the Sick Nursery, Royal Maternity Hospital, Glasgow, for access to the clinical records.

THE CHRONIC PARETIC

BRIAN H. KIRMAN
M.D. Lond., D.P.M.
LATE ASSISTANT MEDICAL OFFICER, FRIERN HOSPITAL

ATTENTION has often been drawn to the large proportion of patients with general paresis who, after artificial fever treatment, survive as chronic inmates of a mental hospital. Thus Lomholt (1944) wrote: “The malarial treatment has created a category of patients which was not known before, namely the defect-cured or stationary paralytics who fill our asylums in great numbers and are a burden to their families and to society.” An early survey by Meagher (1929) of the results of malaria therapy suggested that about a third of the treated patients became chronic hospital inmates. Jossmann (1931), in a survey of 2200 patients, found 25% retained in hospital after treatment, and Moore et al. (1943) a somewhat higher proportion.

Few accounts of the condition of such patients with arrested or slowly progressive paralysis have, however, appeared. The extensive report by Lomholt on a series of Danish cases is an exception. It is therefore considered justifiable to present a summary of the condition of 42 such patients in Friern Hospital (see table).

* Excess globulin present. † No excess globulin. ‡ Benign tertian strain was used in all cases except nos. 2, 3, 5, 15, 27, 28, and 42, where there is no record of the strain. § No. of years after admission, where not same year, is shown in italics.

NAB, 'Novarsenobillon'; NK, 'Neokharsivan'; T, 'Tryparsamide'; Nor, normal; GPI, general paralysis of the insane; TP, taboparesis; hem, hemiplegia; gr, grandiose; dem, demented; dep, depressed; par, paranoid; sch, schizophrenic.

For explanation of numerical results of Wassermann reaction (W.R.) see Mann and Partner (1936).

It might be thought that, with the reduced incidence syphilis and the more extensive use of penicillin, the ults of fever therapy in general paresis would become little practical interest. However, the late war brought steep increase in the number of fresh cases of syphilis, d the early reports on the use of penicillin in neuro- philis are disappointing, probably because the blood- ain barrier presents a formidable obstacle to therapy Neymann et al. 1945). So for some time to come the ults of artificial fever treatment are likely to be of terest to the psychiatrist and syphilologist.

MATERIAL

The 42 patients were all inpatients in Friern Hospital. he average period which had elapsed after treatment 11¹/₂ years, the range 6–18 years. In most cases the ebrospinal fluid (C.S.F.) was normal or almost so, but C.S.F. Wassermann reactions showed a slight change. r colloidal-gold curves started with figures of 2 3, one with 4, and in case 30 twelve years after treat- nt, a patient who could still do a little work in the ital, there was a typically paretic curve with a very ngly positive C.S.F. Wassermann test. In 25 cases blood Wassermann reaction was positive.

As regards the mental picture, 12 patients were gran- and demented, 13 had simple dementia, 3 were ndiose without gross dementia, 2 were depressed, were schizophrenic, and 8, though kept in hospital, not appear grossly deteriorated. The number ed as schizophrenic and paranoid before treat- nt was 7, and 6 after treatment, which supports mholt's view that the incidence of the so-called rstmann psychosis—i.e., schizophrenia developing as result of malaria therapy—is rare.

Of the 42 patients 17 were good workers, 9 were fair rkers, 15 did no work, and 1 was destructive. A good ny of them displayed an almost pathological appetite r manual work, such as scrubbing, sweeping, cleaning, d scouring. They were expansive cheerful inde- tigable workers who would gladly work an extra- dinary number of hours without reward. Fixation at is nearly hypomanic level is common in the treated es of general paresis.

DISCUSSION

Lomholt's picture of mental hospitals with a dense opulation of paretics, their disease arrested by malaria, somewhat overdrawn. Despite the tendency for ch cases to accumulate with the years, they still form London but a small group compared with the great cumulation of cases of chronic schizophrenia which England is a far more serious social problem.

The earlier estimates (Jones 1926, Lilly and Hopkins 927), which attributed 10% of admissions to mental ospitals to syphilis, are either inaccurate or refer to period when the incidence of syphilis was higher Hilliard and Kirman 1941). From my personal observa- ions on admissions to London observation wards in 940–42, less than 2% are due to syphilis. In some ountries where syphilis is more common than in Britain —Simpson (1935) reported 500,000 fresh cases yearly U.S.A.—the problem may be more serious, but it is ifficult to understand how in a country like Denmark, here fresh cases of syphilis before the late war had eached the phenomenally low level of 400 a year, the ental hospitals can be choked with paretics. In fact, hronic paretics in England occupy only a small proportion of the total accommodation, and some of them ppreciably more than earn their keep.

It has been seriously suggested to me that fever therapy should be withheld from the more obviously demented paretics since, even at the best, after treatment they would merely be a burden on the community for years to come. This attitude seems indefensible, because (1) even the most experienced clinician may underestimate the degree of recovery which is possible, and (2) it is clear that the size of the burden thus imposed on the community has been grossly overrated.

It remains true, however, as Nicol and Hutton (1944) showed, that general paralysis is eminently curable, and that the best results are obtained in the treatment of relations of patients with positive C.S.F. but no clinical signs. Each chronic paretic represents a lost opportunity of early diagnosis and cure. It is to be hoped that, with the general recognition by syphilologists of the need for surveillance of the C.S.F., the results of fever therapy will become increasingly favourable and the chronic paretic correspondingly rare.

SUMMARY

A series of 42 cases of chronic paresis who have remained in Friern Hospital for 6–18 years is reviewed.

The average period after treatment was 11¹/₂ years.

Of the 42 patients 24 were doing some work in hospital, and some were very good workers, though in 25 cases the blood Wassermann reaction was still positive, and in 7 the C.S.F. Wassermann reaction still showed slight changes.

Chronic paretics do not represent a heavy burden on the community and should become much fewer with the routine use of lumbar puncture by venereologists, followed where necessary by prophylactic fever treatment or suitable chemotherapy.

TRANSPLANTATION OF TERES MAJOR AND LATISSIMUS DORSI

FOR LOSS OF EXTERNAL ROTATION AT SHOULDER

R. B. Zachary
M.B. Leeds, F.R.C.S.
FIRST ASSISTANT TO NUFFIELD PROFESSOR OF ORTHOPÆDIC SURGERY, WINGFIELD-MORRIS HOSPITAL, OXFORD

The teres major muscle does not seem to have been used often for transplantation, though Boppe (1944) substituted it for a paralysed serratus anticus. In 1934 L'Episcopo described six cases of obstetrical palsy in which he had transplanted the insertion of teres major from the front to the back of the humerus. The paralysis of the external rotators was complicated by an adduction and internal-rotation contracture, and the tendon transference had to be preceded by division of all the contracted tendons on the front of the joint, as described by Fairbank (1913) and Sever (1925). L'Episcopo could not find any previous reference to this tendon transplantation.

The operation described here differs in some respects from that suggested by L'Episcopo, and it may have important applications in the reconstructive surgery of the many brachial-plexus lesions sustained in the war.

L'Episcopo placed the patient prone, with the arm abducted, and his incision was parallel to the lower border

Preliminary Communication

IMMUNISATION OF THE MAMMALIAN EMBRYO

It is generally accepted that young mammals initially receive all their antibodies from the mother, though these are ultimately replaced by other antibodies formed by the gradual development of active immunisation. Some species obtain their maternal antibodies mainly through the placenta before birth, whereas other species —e.g., calves, lambs, kids, foals, and pigs—obtain all their antibodies through the colostrum after birth (Needham 1931, Marrack 1946, Rimington and Bickford 1947, McGirr 1947). Antibodies secreted in the colostrum, the titre of which equals or even exceeds that of the maternal serum (Mason et al. 1930), pass rapidly through the wall of the gut into the circulation of the newborn, with the result that the titre of their serum may equal or exceed that of the mother a few hours after the first feed.

In man, the rabbit, and the guineapig, which species obtain their maternal antibodies mainly through the placenta before birth, the young may acquire further antibodies through the colostrum after birth. Both homologous and heterologous antibodies can pass the placental barrier in these species. The current view is that these antibodies pass through the allantochorionic placenta, and that its permeability depends on the number of tissues intervening between the maternal and fœtal blood-streams. Thus in the ungulates, in which the greatest number of tissues intervene between the maternal and fœtal circulations, the placenta is impermeable to antibodies, whereas in anthropoids and rodents, in which none of the intervening maternal tissues persists and even the fœtal tissues may be reduced, the placenta is permeable to antibodies.

The histological identification of a clot of fibrin in the yolk sac cavity of many 8-, 9-, and 10-day embryos of wild rabbits, though this is probably an abnormality, led to the demonstration that fibrinogen, which clots in oxalated solution in the presence of thrombin, is a normal component of the yolk-sac fluid of the embryos of tame rabbits (Brambell and Mills 1946, 1947). It has since been shown by electrophoresis and the ultracentrifuge that albumin, α, β, and γ globulins, and fibrinogen are all present in the yolk-sac fluid in similar proportions to each other as in the maternal plasma. The presence of these plasma-proteins in the yolk-sac fluid of 7- and 8-day embryos, before the development of the embryonic vascular system, indicates that they are probably derived from the mother. Further evidence of this is the fact that Evans blue, injected into the maternal circulation, becomes selectively attached to the albumin fraction and passes into the yolk-sac fluid (Brambell, Hemmings, Kekwick, and McCarthy, not yet published).

The presence of globulins in the yolk-sac fluid and their known immunological significance suggested that antibodies might pass from the maternal circulation into the embryo through the bilaminar omphalopleur of the yolk-sac wall. We have shown that agglutinin for *Brucella abortus*, whether actively or passively acquired, passes freely from the maternal circulation into the yolk-sac cavities of rabbit embryos on the 7th and 8th days post coitum, before the formation of the allantochorionic placenta. The passage into the yolk-sac in a few hours of the agglutinin passively acquired by the mother, inoculated with immune serum, precludes the possibility of its formation in the embryo.

Agglutinin passes from the mother into the embryo also at later stages of gestation, after the 15th day post coitum, by which time the allantochorionic placenta is fully established and the yolk-sac cavity has been opened up to the uterine lumen by the disappearance of the bilaminar omphalopleur. It has not been possible to determine so far whether this passage at later stages of embryonic development is via the allantochorionic placenta or via the exposed yolk-sac splanchnópleur or both.

The bearing of these results on the current theory of placental permeability is obvious, since it is clear that agglutinins can, and do, pass into the rabbit embryo by a route other than the allantochorionic placenta. Evidently the passage of agglutinin through the embryonic membranes does not depend on the proximity of the maternal and fœtal circulations. Moreover there does not appear to be any morphological reason why the yolk-sac should not provide a possible route into the embryo for maternal globulins in other rodents also; but this is not true for man, in which it is precluded by complete isolation of the yolk-sac wall from the chorion by the exocoele. Some character of the embryonic membranes common to man and the rodents, other than hæmochorial placentation, may explain their similarity in permeability to antibodies.

This work forms part of a scheme of research on prenatal mortality financed by a grant from the Agricultural Research Council to one of us (F. W. R. B.).

Reviews of Books

A Way of Life for the Handicapped Child

EIRENE COLLIS, M.L S.P., M.A.O.T. Foreword by SOMERVILLE HASTINGS, F.R.C.S. Introduction by WINTHROP M. PHELPS, M.D., F.A.C.S. London: Faber and Faber. 1947. Pp. 183. 10*s*. 6*d*.

THE title of this book is somewhat misleading, since it deals only with children handicapped by cerebral palsy, and not with those handicapped by other conditions such as rheumatic heart disease or poliomyelitis. It is a technical treatise, designed to enable the doctor, therapist, or teacher to understand the handicaps and how they may be overcome; and within these limits it is extremely valuable, though not easy reading. The arguments, and some of the sentences in which they are developed, demand close attention if they are to be understood, while some of the author's assumptions are of doubtful validity. Nor is the list of references complete, accurate, or well arranged; but these blemishes are inconsiderable when compared with the implicit evidence of wide reading, keen observation, and hard thought.

Mrs. Collis is a follower, in this field, of Prof. W. M. Phelps, of Baltimore, who has written the introduction to her book. Her practice differs from his chiefly in her reliance on physical education, while Phelps makes much additional use of splinting and of drugs. She recently indicated in these columns the ideas on which her treatment is based,[1] and she explains and expands them in this book. She deals with the attitude of the parents and the important part played by fear, love, and rage in the child, and she analyses the motor defects and their immediate causes and considers the associated sensory defects. Mental defect receives rather less attention than it deserves; in the past all sufferers from cerebral palsy were likely to be dubbed mentally defective and ineducable, while nowadays

of the deltoid and to the long head of the triceps. The teres major was approached on the medial side of the triceps, which needed strong retraction laterally to expose the shaft of the humerus. If the first part of the operation is undertaken with the arm behind the patient's back—i.e., in adduction and *full internal* rotation—the muscle is easily exposed between the long and lateral heads of the triceps, as in Henry's (1945) approach to the back of the humerus. L'Episcopo attached the transplanted tendon to the bone just medial to the lateral head of the triceps, an insertion which does not give a good mechanical advantage. By passing the transplant through a longitudinal slit in the origin of the lateral head of the triceps, it can be inserted on the lateral aspect of the humerus if the arm is externally rotated but not abducted.

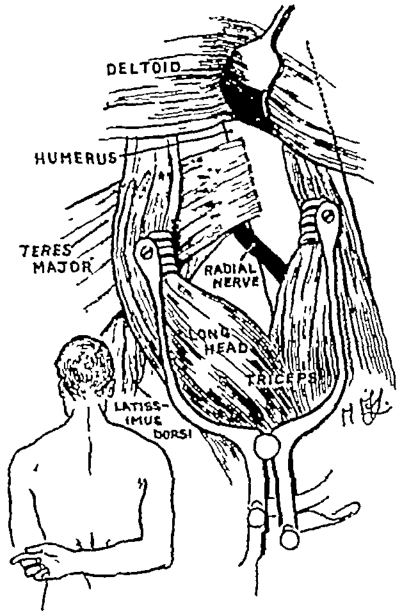

Fig. 1—Retraction of deltoid upwards and separation of long and lateral heads of triceps to expose teres major.

The other feature in which this operation differs from that of L'Episcopo is that both the latissimus dorsi and the teres major are transplanted.

CASE-RECORD

A man, aged 30, had been wounded by a shell splinter in the right side of the neck and below the angle of the right scapula on Jan. 23, 1944. The wound in the chest had caused a hæmothorax, but healing had been satisfactory except for some involvement of the latissimus dorsi in the scar. The neck wound had been complicated by a partial brachial-plexus paralysis affecting C5 and C6. The patient was admitted to the Wingfield-Morris Orthopædic Hospital on June 21, 1944, under the care of Prof. H. J. Seddon. The plexus was explored on July 19, and was found to be in continuity; *later considerable recovery took place, chiefly in the deltoid and biceps.*

On Oct. 8, 1946—nearly three years after the injury—the deltoid and biceps were working against gravity and weak resistance, but the external rotators of the humerus showed no more than a flicker of voluntary power. The patient's chief disability was the tendency of the arm to swing towards the chest when he lifted anything in the right hand. He was a gardener, so the inconvenience was considerable, and he was anxious to have any operation that might improve function.

Operation (Oct. 9, 1946).—With the patient prone and the arm in full internal rotation, the insertion of the teres major was exposed by a reversed S incision over the back of the upper third of the arm, *the posterior border of deltoid being* retracted upwards, and the long and lateral heads of the triceps separated (fig. 1). The radial nerve was identified *at the lower border* of the teres major, and, after a dissector had been introduced in front of the insertion of the muscle, the tendon was detached from the humerus. The latissimus *dorsi* was so intimately blended with the teres major at its lower margin that both muscles were taken together. A confusing anatomical anomaly was *a belly* of muscle running parallel to the upper part of the teres major but on a posterior plane. This muscle was inserted on the posteromedial aspect of the humerus medial to the *uppermost* fibres of origin of t lateral head of the *triceps.* The arm was externally rotat as much as possible, and the tendinous insertions of the ter major and latissimus dorsi were *passed* through a *slit* in t upper part of the lateral head of the triceps (fig. 2). Th *then ran deep to a longitudinal periosteal* band about 1 c wide and were finally fixed to the posterolateral aspe of the humerus with a mattress suture passed through dr holes.

After closure of the wound the arm was fixed in extern rotation with a strut passing from a plaster belt to a lo arm plaster.

After-treatment.—This position was maintained for fi weeks, and after the first three weeks voluntary and farac exercises were performed without abducting or internal rotating t humerus.

Progress.—(Nov. 14 t plaster w removed; t patient cou flex the should and elbo without t forearm swin ing inwar towards t abdomen an could put t hand to h mouth with eas By Dec. 16 t function of t transplant ha improved co siderably; the was no tendenc to interna rotation o the arm whe the elbow w flexed, and t patient coul actively exter ally rotate t humerus from a position of full internal rotation to abo 15° of external rotation. He was delighted with the resu and was convinced that it made the arm more useful.

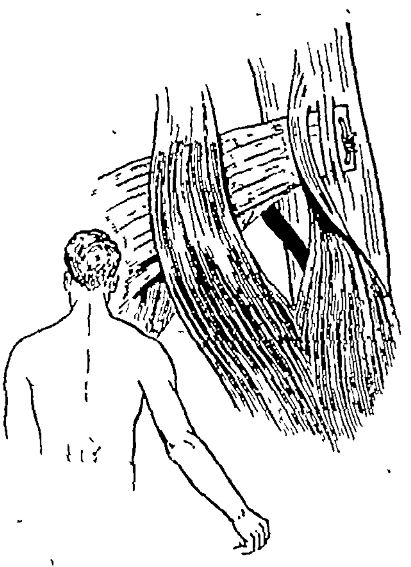

Fig. 2—Detached tendon of teres major and latissimus dorsi passed through slits in lateral head of triceps and periosteum, and sutured to humerus.

COMMENT

A high proportion of brachial-plexus injuries affec the upper roots or trunk of the plexus, and in suc palsies recovery is seldom so good in the external rotator as in the deltoid and elbow flexors. Thus a permanen paralysis or weakness of external rotation is common sequel of this injury, with the result tha the patient cannot lift any object without the forear *swinging in towards the trunk,* a disability whic is aggravated if the external rotators are *subjecte* to greater *stress* by abducting the arm.

SUMMARY

Transplantation of the teres major and latissimu dorsi to the outer side of *the humerus* is suggested t restore external rotation of the arm in certain injurie of the brachial plexus.

The operation is a modification of that described by L'Episcopo and *makes* use of Henry's approach to the back of the humerus.

there is a tendency to say that, apart from a few exceptions, they are all mentally normal. Neither statement fits the facts, though the modern view offers better safeguards for the child; certainly many intelligent children have missed both treatment and education because they were wrongly labelled mentally defective. One way of judging fitness for treatment is to try it for three months or even longer. Research on intelligence tests for these children is urgently needed.

Re-education is discussed in principle and in detail, and the parts played by physiotherapists and occupational and speech therapists are outlined. Rule-of-thumb treatment is useless; the therapists need to be highly intelligent well-trained people with analytical minds and human sympathies. The section on school work gives only meagre information, but there are useful lists and drawings of equipment, and descriptions of exercises and the methods of physical examination.

Although Mrs. Collis writes: "The book . . . has no bearing whatever on the politics, ethics, or administration of new cerebral-palsy schemes," she has been unable to resist a sketch of how the present organisation might be remoulded nearer to her heart's desire. She has wisely not tried to deal with the practical difficulties and complications. Her book will interest therapist, pædiatrician, neurologist, and orthopædic surgeon, but the practical politics of bettering our lamentable facilities for the treatment of cerebral palsy must be worked out in committee.

Diseases of Metabolism

(2nd ed.) GARFIELD G. DUNCAN, M.D., clinical professor of medicine, Jefferson Medical College, Philadelphia. London and Philadelphia: W. B. Saunders. 1947. Pp. 1045. 60s.

THE first edition of this book appeared in 1942 and represented the work of some fifteen contributors. The same authors are largely responsible for the new edition but are joined by six others. The chapters on disorders of thyroid metabolism and on diseases of the kidney are new and good, and though the book as a whole is very much as it was, some of the chapters have been largely rewritten. C. N. H. Long, for instance, has inserted a great deal of new matter into the chapter on carbohydrate metabolism, and this part now contains a clear summary of the biological systems of oxidising enzymes and the importance of the organic phosphates with high energy bonds. The preface notes that the disturbances in nutrition seen during and after the war have "further crystallized medical thinking in terms of total calories, protein, vitamins, minerals and fluid balance." Yet the new chapter on undernutrition, though somewhat longer than the old, will seem dull and academic to anyone who has had any experience of the real thing during the last five years; and the chapter on vitamins contains no mention of the obscure but interesting syndromes which emerged as clinical entities from the prison camps in the Far East. The chapter on mineral metabolism is little changed. The section on iodine, however, has been omitted and appears in expanded form in the new chapter by Winkler on thyroid diseases. Some will not accept all the statements about serum iodine, for those not at New Haven have found it difficult to make satisfactory determinations of iodine in serum; but present ideas about the treatment of thyrotoxicosis are clearly reviewed.

Preventive Medicine and Public Health

WILSON G. SMILLIE, M.D., professor of public health, Cornell University, New York. London: Macmillan. 1947. Pp. 607. 30s.

DR. SMILLIE defines preventive medicine as "those activities that are the direct responsibility of the individual," falling "for the most part upon the family health advisor." It is time that this distinction was made between public health—the old State medicine—which is the function of communities and in which the family doctor does not take an active part, and the prevention of diseases and preservation of the health of individuals, which are his province entirely. Dr. Smillie has little to say about communal hygiene, which is roughly synonymous with sanitation, but deals at length with the more technical medical service of guarding people fr diseases. Broadly, this is the approach to medicine through epidemiology, using that term in wide sense which is now general. Though Dr. Smilli approach tends to be from the pathological rather th the physiological angle—being concerned with t prevention of diseases rather than the maintenance a furtherance of health—this is none the less a m serviceable book. Since health and disease have boundaries, it will be useful to British as well as American doctors, though British students will recogn differences in practice on the two sides of the Atlant Being intended for students and for those in acti medical practice, its statements are dogmatic; lit is said of subjects about which professional epidem logists are still speculating. The book is fully up to d in most particulars, though there is no reference to t action of rubella in pregnancy producing developmen errors in the embryo, and we miss a chapter on geneti In the next edition Dr. Smillie might well mention t British control of rabies, for this is the only example a disease being exterminated by action designed for th purpose.

Bone and Bones—Fundamentals of Bone Biology

JOSEPH P. WEINMANN, M.D., College of Dentist University of Illinois; HARRY SICHER, M.D., Sch of Dentistry, Loyola University, Chicago. Lond H. Kimpton. 1947. Pp. 464. 50s.

OSTEOPHILES, whether clinicians, pathologists, ana mists, or physiologists, have long been looking an authoritative book on their subject, and this goes a fair way towards satisfying them. The are a pathologist and an anatomist, and their d viewpoints thus cover the normal and disordered m phology and morphogenesis of osseous tissue, bon and teeth. The chapter on osseous tissue is in some wa the most disappointing section: so much is left There is scant mention of the intracellular subst its character and formation (for all that it is the re *skeleton from which bone is built*), and *nothing about* t work on X-ray analysis and polarised light which h been so well reviewed by Dallemagne in the series French monographs, *Actualités Biochimiques*. In t section on bones as organs the mechanisms of growth a modelling are well set out, and there is a good account the functional adaptation of bones though not of t changes which occur from adult life to old age.

The rest of the book deals with the pathology of bon and here again there are serious omissions. Osteogenes imperfecta, osteopetrosis, achondroplasia, and heredita multiple exostosis are well described, but dyschondr plasia and the more localised developmental disturbanc are not mentioned. The chapter on adaptational deform ties of the skeleton could scarcely be better, in particul the sections on the changes in scoliosis and the alteratio in the jaw consequent on loss of teeth. The chapte on endocrine, hormonal, and metabolic changes a for the most part sound, but it is puzzling to find front hyperostosis considered as a benign tumour. Nothing said of bone changes in chronic renal failure, Milkman' syndrome, or polyostotic fibrous dysplasia. In th section on neoplasms the effects of tumours on th bones as organs is hardly considered, but the accoun of tumour histology is stimulating. The description o Paget's disease contains no reference to the recent wor on the vascular changes in this condition, nor to Wilton' interesting hypotheses—indeed, the important schoo of Scandinavian osteopathology is to a large exten ignored, though there are ample and well-arrang references to American, English, and German auth

Despite its disappointing omissions, this is an admira book which will be useful to a wide circle of readers.

Recent Advances in Pathology (5th ed. London: J. & Churchill. 1947. Pp. 363. 21s.).—Prof. Geoffrey Hadfie and Prof. L. P. Garrod have introduced an entirely ne chapter on the liver, discussing epidemic hepatitis and al the relationship of hepatic disease to dietary deficiencies the chapter on nephritis has been rewritten, and the chap ters on cancer research revised and rearranged. Addition have been made to the sections on inflammation, the site o antibody formation, and silicosis.

When calcium reserves are depleted.

Restoration of correct metabolism can be effected by the administration of Calcydic. The pleasantly flavoured Tablets and Granules contain calcium and phosphorus together with vitamin D, in carefully balanced proportions.

Calcydic is indicated in all conditions in which there is a deficiency of calcium, and when it is anticipated that extra demands will be made on the calcium reserves.

Calcydic Granules contain calcium mono-acid phosphate 12·5 per cent., dextrose 60 per cent., and vitamin D, 40,000 i.u. per 100 g., and are available in tins of 8 oz. and 16 oz.

Calcydic Tablets contain 20 grs. of the granules and are available in bottles of 40 and 100 tablets.

Europe's Need

WHAT is the present state of continental Europe? w is the health of the people? There can be few ers in this country and fewer still in America could give a clear answer. No reliable opinion be offered without sufficient facts. The reports journalists who have travelled widely in Europe conflicting and often based on hearsay or superl impressions. Doctors returning from the tinent have usually been preoccupied with a e problem in a limited area, and so can give broad review. Public-health statistics, when ailable at all, have generally been collected r difficulties; and, since they have not always n correctly analysed, their interpretation is etimes open to doubt. It has thus been very d to get a satisfactory overall picture of the ent situation, and the International Committee the Red Cross is the more to be congratulated on mpting a general review.

Summarising information from its delegates in all opean countries except Norway, Sweden, Denk, Eire, Luxemburg, Switzerland, Portugal, and aria, the committee paints a gloomy picture.[1] re is still an appalling lack of elementary shelter the areas devastated by war. Essential clothing, especially footwear, is almost everywhere scarce. shortage of food for urban populations is in ral worse than a year ago, owing to the unbroken ession of poor harvests, and—although this is sufficiently stressed—through the sudden ending this year of the vast flow of foodstuffs imported UNRRA into Central and Southern Europe. It is surprising that in many countries the infant-tality rate and general death-rate are still above war levels. (The report claims that the general th rate is actually rising, but it gives no figures.) many towns children are now undersized as a lt of several years of underfeeding, and rickets undoubtedly common, though other vitamin ncies are notably rare. As might be expected, rrhœa and syphilis are still a serious problem many countries, though perhaps not "simply astrophic" as the report suggests. While there been no widespread epidemics of infectious ase, local outbreaks of enteric and diphtheria inue; and malaria, despite vigorous preventive sures, is still prevalent in Italy and the Balkans. haps the most remarkable feature of this post-r period, compared with that after the war of 14-18, has been the general absence of exanthe-tic typhus on an epidemic scale—a phenomenon unconnected with UNRRA's importation of over illion pounds of pure D.D.T. into Europe for the vention of this disease, besides large shipments for the control of malaria.[2] As for tuberculosis, which is without doubt the most important infection in Europe today, mortality figures leave little doubt that it has much increased in many places. At the same time, all such figures need very careful scrutiny. For example, the committee's statement that in the American zone (including the Berlin sector) the tuberculosis death-rate "rose from 20 per 10,000 inhabitants in April, 1946, to 37·5 in April, 1947" seems to be unjustified. For the population of a little over 17 million it would imply between 35,000 and 65,000 deaths in the year, whereas the number of deaths from tuberculosis notified over this period was about 11,000.[3] Also it is not clear why the report singles out Germany as one of the three countries (with Austria and Rumania) where the situation is "particularly disastrous" and pays little attention to Greece and Yugoslavia where the incidence is almost certainly higher. Some of the victims of aggression appear to be in more need of help than Germany, if only because they have suffered privation longer.

The survey ends with a summary of relief needs. No-one who has travelled in post-war Europe would question the continued need for the means of improving local food-production—tools, tractors, draught animals, fertilisers, and seed. Clothing and facilities for feeding children are also required, and (among the medical supplies) surgical instruments, dressings, penicillin, sulphonamides, arsenicals, and D.D.T. The primary need of infants is for dried milk, with sugar and farinaceous foods a very secondary requirement; and in this connexion it is to be hoped that the International Red Cross will consider the recent recommendations of F.A.O. and the World Health Organisation on relief for children.[4] Owing to the termination of UNRRA before its task was finished, the health of many thousands of people in Europe depends for the moment on the efforts of the International Red Cross and other relief agencies: there has been a gap in the larger measures of relief. But the damage of war has gone far deeper than was at first supposed, and the fundamental need is not so much relief as the means to recovery. We must hope that this will yet be met through the great American "investment in humanity" known as the Marshall plan.

Carotid Ligation

THE surgeon generally approaches ligation of the carotid arteries with a feeling of uncertainty; for, as JEFFERSON[5] has pointed out, the pattern of the circle of Willis is incomplete in 8% of normals, and this defect is particularly serious if both anterior cerebral arteries take origin from the same side of the arch. No great reliance is now placed on preoperative tests for the presence of such congenital anomalies. LAHEY and WARREN[6] conclude that the percutaneous compression test of MATAS "is of value only when positive in the production of symptoms." Protracted carotid compression each day, without incident, may yet be followed by postoperative catastrophe—perhaps because the vessel ligation induces temporary intracranial vasospasm. Lambert Rogers[7] holds that electro-encephalography, after temporary ligation, yields better information about the brain anoxia; and this, combined with dynamometer testing of the limb, should be an invariable prelude to final ligation. *But an electro-encephalograph is seldom at hand, and* there are many snags in interpretation. There may, moreover, be no local signs, cerebral ischæmia declaring itself later by epileptiform seizures, blackouts, or mental changes such as inability to concentrate, difficulty in remembering words, and even dementia. Ligation is best carried out under local anæsthesia, since a general anæsthetic may increase cerebral anoxia.[8] For the patient with carotid-vessel injury, however, general anæsthesia is a merciful procedure, for often he is dyspnœic and restless, and certainly he is anxious.

[6] Lahey, F. H., Warren, K. W. *Surg. Gynec. Obstet.* 1947, 85, 281.

In support of his claim that common-carotid ligation is "safe" Lambert Rogers quotes figures from Jefferson, Olivecrona,[9] and Schorstein.[10] Schorstein has said that the danger is cerebral anoxia rather than thrombosis; and the first consideration, especially with emergency ligation, is attention to the general condition, any blood loss being corrected by rapid blood-transfusion. It is odd that Kocher regarded common-carotid ligation as a "death sentence for the old man" whereas so astute an observer as Mont Reid[11] thought such operations safer in the old than in the young. Most of their ligations, however, were for traumatic cases; and the greater optimism which prevails nowadays is perhaps due to the use of massive transfusions. For the ruptured intracranial aneurysm Jefferson[5 12] has long advocated common-carotid ligation, and experience suggests that such "Hunterian ligature" slows the blood-stream enough to cause clotting within the aneurysm sac. Lambert Rogers also favours this procedure, and quotes Magee's[13] review of 150 cases *in which there were 98 survivors from the first* hæmorrhage but 50 of these had a further hæmorrhage, from which 32 died. Such a simple measure seems preferable to applying clips to the neck of the friable aneurysm sac, or to Dandy's use of clips above and below the sac origin.[14] Jefferson, from an unrivalled personal experience, concludes that persistent pain is the danger-signal of the "alive" aneurysm, and this estimate can be confirmed by arteriography.

Ligation of the internal carotid is more risky. Statistics are confusing, for it is often hard to decide whether a death has been due to the operation or to the hæmorrhage for which it was usually undertaken. In 49 cases collected by Schorstein 8 patients died and 11 developed paralysis. Lahey and Warren think this ligation very hazardous; and for carotid-body tumours they recommend exploration, leaving the tumour alone if dissection indicates that internal-carotid ligation will become necessary. While Schorstein holds that embolism is not a frequent cause of disaster following ligation, Dandy and
Rogers both consider it important. Rogers ad
resection of the cervical segment of the int
carotid at the same time as ligation, so as to re
a stagnant cul-de-sac. The vessel, however, is d
situated and is crossed by important nerve bran
and the patient is still left with an intracranial
stump. Anticoagulants, as Lichtenstein points
may have a place, particularly in the traumat
secondary-hæmorrhage case, where low blood-pre
over a long period has permitted extensive throm
within the cerebral arteries. Symptoms of slow
late onset may indicate venous thrombosis w
the sluggish stream,[15] and they point to the nee
anticoagulant therapy.

The frequency with which anastomosis of in
arteries is now successfully undertaken suggests
surgeons have been too gloomy over the prospec
vessel repair. Preliminary control is essential,

Drug-induced Statements

ENGLISH law does not allow an accused person's ions or admissions to be used against him they were freely and voluntarily made; the n of proof is on the prosecution to satisfy the that they were not induced by any promise of our or advantage, or by the use of fear or threats. or may loosen a man's tongue; the sheer fatigue long-continued questioning or the use of "third " methods may break down the reticence or ge the defence of persons detained by the e. The report of the Royal Commission on ce Powers and Procedure, published in 1929, con- and emphasised the rule that this kind of to obtain confessions is not tolerated in this try. In the United States it does not seem ain that their use will be prohibited—so long as they employed in a manner calculated to obtain truthful ts. Do the two Anglo-Saxon communities differ their views of fair play to the accused? If so, is difference due perhaps to the varying levels of ess in the enforcement of the law? Is it that in this country are content with the orthodox thods because our Scotland Yard and our local ective staffs manage to attain a reasonably high portion of convictions in cases of crime?

These questions are prompted by an interesting cle,[1] well documented with references to American e law, by Mr. LEON M. DESPRES, a member of the inois bar. Here is a detailed study of the so-called "truth drugs" or "lie-detectors." If it can be med as the experience of anæsthetists or obstet- ians that, under the influence of certain drugs, a tient will make spontaneous and revealing dis- sures, and if similar stimuli could succeed in cases amnesia where a man cannot recall his own name address, or in cases where the psychiatrist is seeking key to repressions, why not apply the like process defence of the community against the criminal? A year ago, says Mr. DESPRES, the prosecuting thorities in Cook County, Illinois, caused a psychia- ist to give a series of injections of sodium 'Pentothal' William Heirens, a 17-year-old boy arrested in an tempted burglary and suspected of some sensational rders. This elicited, it is said, an admission that had committed three murders and a number of rglaries later found to exceed five hundred. When is led to his written confession and his pleading ilty, the newspapers were bound to proclaim the ccess of the new "truth serum" in promoting the entification and conviction of a criminal. Nor need e "serum" be the monopoly of one side only. Dr. ROBERT E. HOUSE, whose writings on this subject are thoritative, recorded twenty years ago that a ysician injected scopolamine into two convicts in Dallas county gaol and established to his satisfaction at they were not guilty of the crimes charged. Dr. W. F. LORENZ,[2] writing in 1932 on Criminal Confessions under Narcosis, considered the use of drugs far more effective in clearing the innocent than n convicting the guilty. But in 1926 the supreme court of Missouri rejected a defendant's offer to support his innocence by testimony of statements made while under the influence of a drug. A doctor was ready to depose that the accused had, under the influence of a "truth-telling serum," denied his guilt. "We are not told," said the court sceptically, "from what well this serum is drawn or in what alembic its alleged truth-compelling powers are distilled. Its origin is as nebulous as its effect is uncertain. . . . The trial court . . . ruled correctly in excluding this clap-trap from the consideration of the jury." Mr. DESPRES thinks that this decision would be universally followed by other American judges today. "The unreliable nature of the statement and the suggestibility of the subject would make any court hesitate to disorganise a trial by allowing admission. . . . Although widely used by police, by employers, by insurance companies and others to detect deception, the 'lie detector' test has not yet established itself as sufficiently trustworthy to be admissible in evidence." One court has refused to admit the tests of a "lie-detector" even when both sides were ready to let them be put in.

Textbooks on both sides of the Atlantic deal with the forensic use of information obtained by using drugs to get statements which in themselves are inadmissible. It is unnecessary to remind medical practitioners that an injection against the will of the patient is an assault. Mr. DESPRES raises another question: if in the course of the proper medical use of a drug like sodium pentothal the physician hears a confession of crime, what is his duty? Mental patients include a proportion who are, in the legal sense, criminals as a result of mental ill health; the question is therefore by no means academic. The Hippocratic oath and the acceptance of professional secrecy give the answer. For the rest we may note his conclusion that, while the therapeutic use of sodium pentothal and related drugs must be encouraged, their injection into unconsenting criminal suspects is premature until society fully accepts the principle and practice that law-breakers are to be treated and corrected rather than punished, and that the aim of criminology should be the speedy cure and rehabilitation of the criminal without regard to traditional ideas of retribution and public punishment.

Group Practice

IN the United States group practice has been developed on a scale unknown in this country. In their latest broadsheet[1] P.E.P. attribute its growth partly to the desire of doctors to provide a full service in undeveloped regions—particularly rural areas—and partly to their desire, by pooling resources, to provide a service within the means of their patients. A third motive has been the wish among doctors for coöperation and consultation; day-to-day consultations are supplemented by staff meetings and good record systems. Within the group financial competition is eliminated, though friction may still arise over the allocation of fees, and personalities may clash: some doctors are regarded as unsuitable for group work because they are uncoöperative by habit or temperament. Conditions in the U.S.A. are very different from those that will prevail in Britain with the new health service; but P.E P.'s report may be profitably studied for its lessons on the benefits and drawbacks of close integration in medical practice.

because the vessel ligation induces temporary intracranial vasospasm. Lambert Rogers[7] holds that electro-encephalography, after temporary ligation, yields better information about the brain anoxia; and this, *combined with dynamometer testing of the* limb, should be an invariable prelude to final ligation. But an electro-encephalograph is seldom at hand, and there are many snags in interpretation. There may, moreover, be no local signs, cerebral ischæmia declaring itself later by epileptiform seizures, blackouts, or mental changes such as inability to concentrate, difficulty in remembering words, and even dementia. Ligation is best carried out under local anæsthesia, since a general anæsthetic may increase cerebral anoxia.[8] For the patient with carotid-vessel injury, however, general anæsthesia is a merciful procedure, for often he is dyspnœic and restless, and certainly he is anxious.

In support of his claim that common-carotid ligation is "safe" Lambert Rogers quotes figures from Jefferson, Olivecrona,[9] and Schorstein.[10] Schorstein has said that the danger is cerebral anoxia rather than thrombosis; and the first consideration, especially with emergency ligation, is attention to the general condition, any blood loss being corrected by rapid blood-transfusion. It is odd that Kocher regarded common-carotid ligation as a "death sentence for the old man" whereas so astute an observer as Mont Reid[11] thought such operations safer in the old than in the young. Most of their ligations, however, were for traumatic cases; and the greater optimism which prevails nowadays is perhaps due to the use of massive transfusions. For the ruptured intracranial aneurysm Jefferson[5 12] has *long advocated common-carotid ligation, and* experience suggests that such "Hunterian ligature" slows the blood-stream enough to cause clotting within the aneurysm sac. Lambert Rogers also favours this procedure, and quotes Magee's[13] review of 150 cases in which there were 98 survivors from the first *hæmorrhage but 50 of these had a further hæmorrhage,* from which 32 died. Such a simple measure seems preferable to applying clips to the neck of the friable aneurysm sac, or to Dandy's use of clips above and below the sac origin.[14] Jefferson, from an unrivalled personal experience, concludes that persistent pain is *the danger-signal of the "alive" aneurysm, and this* estimate can be confirmed by arteriography.

Ligation of the internal carotid is more risky. Statistics are confusing, for it is often hard to decide whether a death has been due to the operation or to the hæmorrhage for which it was usually undertaken. In 49 cases collected by Schorstein 8 patients died and 11 developed paralysis. Lahey and Warren think this ligation very hazardous; and for carotid-body tumours they recommend exploration, leaving the tumour alone if dissection indicates that internal-carotid ligation will become necessary. While Schorstein *holds that embolism is not a frequent* cause of disaster following ligation, Dandy and Rogers both consider it important. Rogers ad resection of the cervical segment of the int carotid at the same time as ligation, so as to re a stagnant cul-de-sac. The vessel, however, is d *situated* and is crossed by important nerve bran and the patient is still left with an intracranial stump. Anticoagulants, as Lichtenstein points may have a place, particularly in the traumat secondary-hæmorrhage case, where low blood-pre over a long period has permitted extensive throm within the cerebral arteries. Symptoms of slow late onset may indicate venous thrombosis w the sluggish stream,[15] and they point to the nec anticoagulant therapy.

The frequency with which anastomosis of in arteries is now successfully undertaken suggests surgeons have been too gloomy over the prospec vessel repair. Preliminary control is essential, "stick sponges," as recommended by Lichtens are useful for temporary hæmostasis to clear the With low wounds they can be passed behind clavicle to permit pressure, while the field is enla if need be, *by excision of the sternoclavicular* j Such "sticks" are also of value for locating venous bleeding site; hurried grasping of vei particularly dangerous, for the hæmostat is like tear even more the thin walls. Opinion now s opposed to the deliberate associated jugular *ligature;* Lambert Rogers *declares that* ele encephalography shows this to increase brain an Little is known about the possible valu cervical sympathectomy coincident with the liga for few neurosurgeons appear to practise it traumatic carotid aneurysms Learmonth[16] perf *a sympathectomy on the opposite* side, and s days later a sympathectomy on the side of aneurysm operation; and at the recent Internati Conference of Surgeons one speaker showed art grams indicating that this procedure promotes cor vasodilatation. Olivecrona believes that periart *sympathectomy and carotid-sinus* excision ar definite value at the time of the ligation. The sur may be compelled, particularly in traumatic inju to ligate both vertebral and common-carotid ar at the same time: Learmonth[17] has reported such case, in which an uninterrupted convalesc *was followed by pattern* seizures, "blackouts," total invalidism. Shumacker[18] has done an ap ently successful double artery ligation, but g warning that ligation of the vertebral artery may itself cause cerebellar degeneration without evid of embolism or thrombosis. The vertebral ar may be affected in Blalock's type of operation congenital pulmonary atresia, after which tempor brain effects have in fact been observed. Correla studies of the carotid and vertebral arteries are particular importance with basilar-artery aneurys "For these," as Jefferson puts it, "surgery has answer"; and this is reflected in McDonald Korb's[19] 143 collected cases of which 139 were "p mortem discoveries."

apposed through sucking, but when chewing starts the two move farther apart and snoring becomes possible with mouth-breathing. In adults muscle tone is an important controlling influence, irrespective of nasal airway. The position of the tongue is governed to some extent by the shape of the mandible; and it is also affected by sleeping on the back and by deglutition. Snoring ceases during the act of swallowing and is resumed only if the tongue returns to the critical position for palatal vibration. There may be a central reflex governing the tone of the glossopharyngeal musculature; and the fall in the production of adrenaline during sleep, with the resulting diminution of muscle tone, may explain some types of snoring. Minor nasal disorders leading to thickening of the mucosa are an important factor.

Mr. I. G. Robin, in an address on Nov. 7 to the section of laryngology of the Royal Society of Medicine, suggested that in treatment any anatomical intranasal obstruction should be removed, and any allergic condition corrected. The withdrawal or reduction of irritants such as tobacco, and attention to diet and habits in plethoric individuals help to prevent mouth-breathing. At night children who have acquired the habit can wear an orthodontic splint, or a strip of strapping across the corner of the mouth. In adults where loss of muscle tone is the important factor breathing or phonetic exercises may retrain neuromuscular control; or an orthodontic splint may prevent the tongue and palate assuming their critical relative positions. Anything to stop the snorer from rolling on to his back is useful: the old remedy of a cotton reel sewn into the back of the pyjamas has been suggested. The heroic method of injecting sclerosing solutions into the palate and fauces has been used, but it is hardly to be recommended.

TRICHOMONAS VAGINITIS

THE treatment of *Trichomonas vaginalis* vaginitis is often unsatisfactory owing to faulty diagnosis, inadequate prophylaxis, and improper application of whatever remedy is used. Reich, Button, and Nechtow[1] have reviewed in detail 153 cases out of 2080 examined for suspected infection, and their conclusions are instructive. Careful history-taking and examination may reveal certain characteristic features, such as an irritating vaginal discharge with secondary vulvitis and pruritus; sometimes bladder symptoms are present, suggesting urethritis and trigonitis; and in bad cases dyspareunia, spasm of the vulva, and a feeling of discomfort in the vagina are also complained of. Inspection of the vagina shows the characteristic thin yellow frothy discharge, which may be profuse. The vault of the vagina and the cervix are acutely inflamed, with pinpoint petechial patches which bleed on instrumentation; the cervix often shows coincident lesions such as erosions, polypi, and cysts. The clinical diagnosis is confirmed by passing an unlubricated speculum and taking a hanging drop of vaginal secretion from the posterior fornix with a long tapering glass tube and rubber suction bulb. The number of trichomonads present in a high-power field varies from less than 3 to more than 8. If the bladder is infected the hanging-drop examination is made from a centrifuged catheter-specimen of urine; a gram stain should be done to determine the presence of secondary infecting organisms.

An exact diagnosis having been made, Reich and his colleagues place the patient on a course of home treatment, after preliminary outpatient treatment. The latter involves cauterisation of any cervical erosion, removal of polypi, and cauterisation of cysts. The Skene's ducts, if infected, are fulgurated, and the vagina is dried and insufflated with powder containing 20% finely pulverised mild silver protein, 40% kaolin, and 40% β-lactose. The patient is then told to douche with a weak solution of vinegar (1 drachm to 1 pint): to insert every night a capsule containing the same mixture of silver protein, kaolin, and β-lactose; and to return for re-examination in a week. Certain important hygienic instructions are given: (1) the anus must be cleansed from before backwards; (2) the hands must be washed before any vaginal manipulation such as inserting tampons or pessaries; (3) the external genitalia must be washed before douching, and the douching apparatus must be sterilised: (4) intercourse must be regarded as a possible source of reinfection; and (5) the bath must be scrupulously clean. There is no doubt that the rectum, the mouth, and the penis are all possible sources of infection. Douching and the insertion of medicated pessaries must be continued during menstrual periods: every gynæcologist knows that infections of the lower genital tract tend to flare up after a period, and interruption of treatment may be one cause. Proved cases of trichomonas infection should attend for observation for six months. For this régime Reich claims 98% successes.

RESEARCH IN POLAND DURING THE OCCUPATION

SUBOPTIMAL conditions, whether they are social or technical, seldom defeat the keen observer or research-worker. During the late war many original observations were made, with primitive equipment, in prisoners' camps and in even more difficult circumstances. Recently published in an American journal are two papers based on work done in Poland in 1942 by Dr. Ludwik Fleck.

The first,[1] written with Zofia Murczynska, deals with the agglomeration, in shed blood, of the white corpuscles into small clumps of the same types. When the leucocyte layer from centrifugalised citrated blood was incubated at 37°C, and specimens were removed at short intervals and examined as thick films, it was found that after 3–5 hours leucocytes of the same type tended to agglutinate in small groups—i.e., each group consisted almost entirely of polymorphonuclear leucocytes, or lymphocytes, or some other variety. When he first described the phenomenon in 1942 Fleck called it "leukergy," and he now lays down certain standards whereby it can be estimated, taking into account the proportion of white cells in a preparation which are clumped and the average number of cells in each group. The lowest value is given to preparations showing only an occasional agglomeration of white cells with 3–4 cells in each clump, and the highest value is reserved for preparations showing almost all the white cells clumped in groups of 6–15. In acute inflammatory processes the leukergic value tended to rise with the leucocyte-count and the red-cell sedimentation-rate but the rise appeared to persist longer; and in animals injected with bacterial antigens it followed the same lines. The technique of estimation is not given in full detail, but the method suggests that the experimental error may be considerable. Nevertheless the observations are interesting, and possibly more extensive and controlled experiments would indicate relationships with allied phenomena.

In the second paper[2] Fleck describes the presence in the urine of typhus patients of a substance having the characters of a specific antigen of typhus rickettsiæ. This substance may appear in the first days of the disease and in amount sufficient to give a characteristic precipitin reaction with a typhus serum. Injected into rabbits, it may give rise to rickettsial, and also proteus OX19, agglutinins. By suitable treatment of the urine the antigen may be concentrated so that it can be used as a prophylactic; indeed by this means Fleck prepared enough antigen to immunise some 500 inmates of a concentration camp in Poland during the war when no other prophylactic was available, and though it was impossible to keep proper records there was some evidence of its value. The most important of these

TOWN PLANNING

THE success of town planning may be measured by the number of people saved from hospital. This view was put forward on Nov. 5 by Mr. Arthur Ling, senior planning officer in the L.C.C.'s architects department, in a lecture at the Royal Institute of Public Health and Hygiene. The purposes of town planning, he suggested, are to eradicate the environmental causes of sickness, and to create a harmonious and healthy background for an enjoyable life. Over four-fifths of the population live in urban areas, where, owing to the high value of land, sites have been intensively exploited. In 1936 10% of families in England and Wales were found to be overcrowded, while in some parts of Scotland the proportion was even higher: the figure for Clydebank was 44% and for Motherwell 40%. It is not sufficiently known that just before the late war no less than 60% of families in the County of London were sharing houses in non-structurally separated buildings; the sharing of accommodation, and notably of a kitchen, is the source of constant friction.

Hitherto the better properties have usually been sited on *high ground, while overcrowding* has been greatest on low ground. Owing to the larger cost of land on high ground local authorities have often been compelled to acquire for housing estates low-lying sites close to railways or industries. More open space is needed in towns; statistics prove that death-rates are highest where there is least open space. In the last fifty years cities have sprawled out into the countryside: the town has been taken to the country. Now the trend must be reversed and the country brought to the town. The key to redevelopment is a national policy for the redistribution of industry and population. Workers now commonly live far out from the centre of cities, but the industries which employ them remain at the centre. Workers thus have an excessive amount of travelling, with consequent expense, loss of time, tiredness, liability to infection, and tendency to a time-killing attitude of mind. Two-thirds of London Transport's traffic is accounted for by the movement of workers. During the late war Mr. Ernest Bevin, as Minister of Labour, estimated that if this travelling time could be halved production would rise by 10%. Staggering of hours, transfer of workers in multiple firms to branches near their homes, and improvements in the transport services would relieve the congestion. But the only real solution lies in planned decentralisation of industry to new towns, and in local decentralisation to the suburbs, whereby as many employees as possible would live near their place of work, and the flow of one-way traffic to and from towns at the start and end of the day would be superseded by a two-way flow. A more obvious defect in the present design of our towns is reflected in the figures for road accidents. Of 6000 fatal accidents in 1936–37, two-thirds happened in urban areas. Town roads were designed for horse traffic, and the value of new arterial roads has been nullified by ribbon development. Pedestrians should be segregated by the construction of by-passes, the reservation of certain roads for fast traffic, and eventually perhaps by the building of traffic lanes on different levels. Improvements in the main roads will make possible the formation of neighbourhoods or precincts; happy examples of precincts are to be found in the Temple, Lincoln's Inn Fields, and the colleges at Oxford and Cambridge. The concept of the neighbourhood has now been generally accepted. These should be as far as possible self-contained, and they should include community buildings. In planning health centres the usual proposal is that one centre, with 6–8 doctors, shall serve about 20,000 population. This does not fit in, however, w
the structure of the neighbourhood, with its 6000–10,
population; and Mr. Ling thought that centres serv
so large a group might be too remote from the everyc
activities of its users.

The town-dweller is constantly exposed to the din
traffic, with its subtle but serious effects on heal
Every transport vehicle should be tested for n
emission; and where noise cannot be eliminated
policy of segregation should be pursued. Thro
atmospheric pollution central London gets only half
much sunshine as Kew. Two-thirds of the pollut
is due to the domestic chimney. The nuisance could
controlled if households gave up their open fires
used smokeless fuel. Perhaps district heating mi
be developed; a great deal of heat now lost from
power stations could be distributed on this basis. L
winter's fuel crisis, with the resulting ban on the
of electricity, showed to what a large extent offices r
on artificial lighting. Daylight standards should
improved; and a new code has been prepared
the Ministry of Town and Country Planning. In t
as in other aspects of town planning, Mr. Ling conclud
the planners should work in close partnership with th
responsible for the health services.

REGIONAL ILEITIS

REGIONAL ileitis is a rare disorder, but, as Profes
Merke shows in his latest report,[1] it is not so rare that
can afford to forget it. Of the 9 cases he describes
had been submitted to operation on the mistaken di
nosis of acute or chronic appendicitis. Merke holds t
this error, and the usually long delay in diagnosis, wo
not be encountered if the condition were more genera
borne in mind. The duration of symptoms in his ca
varied from four weeks up to at least eleven years;
the symptoms were strikingly uniform, consisting
colicky pain and diarrhœa. Among the other *diagnos*
points are a consistently positive benzidine *test in*
fæces and, often, a positive indican test in the urin
the blood-sedimentation rate is increased. But diagno
hangs on the radiological findings: barium is delayed
the lower *ileum*, and advanced stenosis of the ile
close to the ileocæcal valve may be observe
sometimes an "ulcer crator" can be defined. Path
logically, the naked-eye appearance resembles that
tuberculosis; and Merke is indeed inclined *to rega*
this obscure lesion as tuberculous. In 5 of his 9 ca
there were manifestations of *tuberculosis* elsewhere
the body; and in 2 further cases *there was a history*
tuberculosis in the patients' households.

SNORING

SNORING, though a widespread habit, has had litt
attention from the medical profession; yet it is *oft*
a nuisance to the snorer himself, and it is *certainly*
nuisance to his associates, as many found during t
war *in the* community life of the Services. To so
extent it is a disorder of civilisation; apparently wolv
never snore, whereas the domestic dog does. It is al
a disorder of certain times of life: the child is often
snorer, the adolescent rarely; the practice is *common*
in late middle life and old age.

The noise is produced by vibration of the *soft* pala
and posterior *faucial pillars*, usually during inspiratio
through the mouth. A reservoir of air is formed *in th*
nasopharynx, and vibration occurs when a certain *relati*
position of the palate and tongue is reached. The dampin
effect is produced by the texture of the palatopharynge
musculature together with the thickness of the tissue
involved, of which the mucosa is the most *importan*
The normal resting position of the tongue and *so*
palate varies with age. In the babe the two structures a

Reconstruction

HOSPITAL BUILDINGS OF TOMORROW

FROM A CORRESPONDENT

> "Si tous les perfectionnements de la technique moderne y ont été appliqués dans les installations de traitement, ils n'ont pas fait oublier l'élément psychologique si nécessaire au malade qui entre là dans une grande maison accueillante, disposée au milieu de la nature toujours vivante, au lieu d'avoir le sentiment d'être happé par une mécanique.
>
> "Au monstrueux entassement des malades dans des constructions éclipsant et blessant la nature, dont l'architecture semble vouloir frapper d'étonnement les populations, il semble préférable d'appliquer à de telles réalisations une conception plus humaine, plus française aussi."
>
> —A. LABOURIE, *Architect. française*, Oct.–Nov., 1945, p. 61.

WHEN are we going to evolve a really satisfying design for our greater hospitals ? Two at least of those in the metropolis are to be rebuilt as soon as conditions permit, and those responsible are already busy scheduling their requirements. Charing Cross is to go to Harrow, and St. George's—the old building looks remarkably distinguished in its new coat of cream paint—is to move to Tooting. And in several of the great cities of the provinces similar projects are afoot.

The tendency towards a functional simplicity of design seems to have set in strongly, and the trends of the 1930's come out clearly in the great rectangular blocks of the Queen Elizabeth at Birmingham and the St. Helier in Surrey. The Queen Elizabeth contains some 720 beds and St. Helier was planned for 862, but one cannot visit these hospitals without a feeling that something has been sacrificed ; well designed and well finished as they are, they lack something of repose and dignity. They do not settle happily into their surroundings, and one feels that in wintry English weather the cold winds must blow icily around the wards. There are still hospitals to be found, like St. Thomas's or King's College, which manage to express in their architecture a more satisfying tradition. Must we, in the interests of modernity and efficiency, expect to see more Queen Elizabeth's and St. Helier's or other variants on the Continental and American models ? To say this is certainly not to disparage the architects, for they have had to conform to current conceptions of what is required in hospital construction.

LOSSES

What exactly is it that has disappeared in the interests of utility ? First, there is the break with tradition. The traditional building for community life in this country, not only for hospitals but for colleges and schools, is the quadrangle or some modification of it. No-one can be familiar with the quadrangles and courts of Oxford and Cambridge without knowing that they possess qualities of repose and peacefulness for which height is no substitute. Mere height is barrack-like and forbidding. Does it matter ? Opinions will differ, but it is hard to imagine the student nurse of today acquiring much affection for the gaunt lines of her utility home. Perhaps it matters more than one would at first sight suppose that the hospital buildings should link themselves by an easy association to our famous schools and colleges.

Secondly, there is the loss of intimacy with lawns and trees with every story up from the ground. The sunlight on the foliage becomes less accessible, until the distant prospect of Birmingham chimneys or suburban London dormitories wholly replaces it. Compare with this the wide windows and garden outlook of some of the wards at King's College, or the London plane trees that glitter in the sunlight outside the wards of Queen Square ; even the hard-hearted must admit that perhaps there is something in it, and that perhaps patients do after all feel more comfortable and more at home down on the garden level. It is a factor in the attraction of the cottage hospitals that so often the wards are at the garden level.

Thirdly, there is the loss of quiet. Steel construction is admittedly responsible for difficulty in controlling noise, and despite every effort to apply modern methods of insulation, the fact remains that the modern steel and concrete hospital is noisier than the old buildings of brick and stone. It is probably colder too, and requires more heat to make it comfortable, though the effects of this are often masked by the existence of modern boilers and central heating.

Fourthly, there is the monotony that is too often associated with utility. Repetition and uniformity in such matters as the design of windows is not in itself a bad thing : one has only to recall the façade of the Royal Crescent at Bath and the long lines of Georgian windows that so easily achieve distinction. But to pass in one of our modern hospitals from one ward to another in exactly the same style and decoration, and to pass from one nurse's bedroom to its twin next door, and so on floor after floor, is to breathe an atmosphere against which surely the spirit of man rebels. Uniformity can, in fact, only be redeemed by a certain generosity of treatment, and the box-like structure of the modern steel-framed hospital proceeds regardless of all but economy. And yet it is not cheap ; it is indeed fantastically expensive. A simple utility nurses' home costs today something like £500 per nurse, without trimmings of any kind. The more luxurious examples like those of the Queen Elizabeth would cost £700–800 per nurse. Compare this with the cost of building good small modern houses !

Internally too the long corridors and the magnificent recreation halls in the nurses' homes seem to express the soulless efficiency of the cosmopolitan hotel rather than the homeliness and comfort of so many of our older English buildings. Pictures are conspicuous by their absence. Sometimes indeed a print of flowers or a Medici reproduction has been brought in to fill the void, but much more is surely called for. Where is there any hint in these modern hospitals of the great traditions of English medicine and of English nursing ? The authorities seem to have forgotten that the hospital with its hundreds of student nurses and other trainees is also an educational undertaking of no mean size. In all education visible contact with the past and a sense of participation in present progress are needed if the newcomer is to feel part of a greater whole. Where are the quiet corners where the nurse can pick up and peruse the history of the hospital, or, if she be so disposed, copies of the current medical publications ? Where are the prints of the old buildings, and the portraits and stories of those that have passed through the school in days gone by and who have achieved distinction ? Where is the list of last year's prize-winners, or where even are the miscellaneous and intriguing papers that clutter the notice-boards of the porters' lodges in the colleges of our universities ?

THREE TRENDS

But this is a digression. Let us return to the factors that seem to be steering us towards this cosmopolitan uniformity of construction, which seems likely to make our hospitals of tomorrow giants dwarfing all natural objects of the landscape. The factors seem to be pretty clear.

First, there is the tendency towards increase of size. It would take us too far afield to go closely here into the arguments in their various applications to the teaching hospital, to the large all-purpose general hospital, and to the smaller local hospitals ; but it may be that the tide is now turning, at any rate in the case of the general hospital. To judge by the latest surveys opinion in America at any rate seems to be hardening observations is, of course, the early immune reaction, which was independently described by Leon[3] in Mexico in 1942. Unfortunately this does not seem to be found often enough in the less severe cases to give it much diagnostic value. It is in the severe case where the kidney is more affected that one would expect urinary excretion of rickettsial substances to be greatest.

Fleck mentions false positive results both with normal serum and with urine from non-typhus cases; but the test is simple to carry out and in a typhus outbreak its extended trial may yield valuable information.

HEALTH IN THE POTTERIES

LEAD poisoning and silicosis have long been known to be the main occupational health risks in making and decorating pottery. Lead enters into the composition of glazes, and free silica in various forms into both glazes and pottery bodies. Ground flint, which contains a high percentage of free silica, has also been freely used in pottery-making for various other purposes such as the "placing" of biscuit ware (or unglazed pots) for firing in ovens.

Since the beginning of the century much progress has been made in reducing the incidence of lead poisoning and silicosis by two standard methods—namely, exhaust ventilation to remove dust from the workers' breathing area, and replacement of the noxious agents by less harmful ones. Leadless glazes have in many cases replaced those containing lead, and a further innovation has been the low-solubility lead glaze, the principle of which was discovered about 1900 by Sir Edward Pope, at that time Chief Government Chemist, when he fused raw lead compounds with silica to produce a "frit" or lead silicate which is relatively insoluble and therefore less poisonous than red or white lead. The result of these improvements can be seen in the figures for lead poisoning in potteries: in 1900 210 cases with 8 deaths were notified, but in 1944 and 1945 none at all. Likewise the practice of using ground flint for the placing of biscuit ware for firing was productive of much dust and many cases of silicosis; but it has been discovered within the last fifteen years or so that powdered alumina, which has refractory properties comparable with those of flint or quartz, will serve the purpose equally well, and its dust is relatively harmless when inhaled by the workers. Since then flint has been replaced by alumina for placing biscuit ware in most of the potteries in the country.

The new code of regulations issued by the Ministry of Labour and National Service[4] crystallises the advances made in preventive measures during the present century and should bring any backward potteries into line. These regulations prohibit the use of raw lead glazes in the manufacture and decoration of pottery after Oct. 7, 1948, and in the manufacture of glazed tiles after Oct. 7, 1949. The actual wording is that "no glaze which is not a leadless glaze or a low solubility glaze shall be used" after the specified dates. Again, after Jan. 7, 1948, ground or powdered flint or quartz shall not be used (1) for the placing of ware for the biscuit fire; (2) for the polishing of ware; (3) as an ingredient in a wash for saggars, trucks, bats, cranks, or other articles used in supporting ware during firing; or (4) as a dusting or supporting powder in potters' shops. Another important regulation is that, with certain exceptions, ground or powdered flint must not be brought into a factory in a dry state, but must come in as a slop or paste. Unfortunately this prohibition cannot be made absolute, and a subsection provides that dry powdered flint or quartz may be brought into a factory if the containers are so sealed and enclosed as to prevent the escape of dust. The subsequent processes of handling and mixing to form the body of the ware must also be done in such a way that no dust escapes into any place where people are employed

The new regulations should go far to make the potters ancient craft a more healthy one.

TOBACCO ANGINA?

THIS unfortunate term, originally introduced nearly fifty years ago by Huchard,[1] dies hard. One reason i that there is still no convincing evidence of a direc relation between smoking and angina pectoris. It ha proved almost impossible to evolve an experiment tha will produce a definite "yea" or "nay," and eve when man himself is the experimental subject there ar many factors to complicate the issue. Thus Pickering and Sanderson,[2] in a detailed study of one patient, show that though in this individual angina pectoris followed smoking it did so only just after the subsidence of an attack of pain precipitated by exercise, when the blood-pressure and pulse-rate were still raised.

Even the many reports which attribute changes in the electrocardiogram to a direct effect of smoking on th heart are under suspicion, because care has not been taken to exclude the possibility—often the probability—of these changes being due not to the smoking but t the changes in pulse-rate which it induces. Impressed by the absence of convincing electrocardiographi evidence, Bryant and Wood[3] have studied 16 patient with coronary disease, all of whom were smokers bu none of whom gave a history suggesting a relatio between their anginal symptoms and the use of tobacco. Unipolar limb and chest leads were used and electro cardiograms were taken at rest before and after th smoking of two cigarettes. In 2 patients angina pectoris accompanied by electrocardiographic changes, followe this procedure: in one of these the pain was induce only by smoking; in the other it was induced by exertio and by smoking. In the patient with "tobacco angina" the pain and electrocardiographic changes were no associated with any rise in pulse-rate, and some te months later he reported that he had given up smokin and had had no further attacks. It is dangerous to argu from the particular to the general, especially when th particular means one case; but extended investigation on these lines might help to solve a vexed problem. Unless, and until, such an investigation shows tha smoking alone can produce angina pectoris, clinician will be justified in contending that, per se, it is not a important factor in the genesis of this condition. Si Maurice Cassidy, from an analysis of 1000 cases o coronary disease seen in his own practice, has state that "so far as so-called 'tobacco angina' is concerned I have never encountered such a condition"[4]; and even in these days of laboratory medicine such a statement must be given serious consideration.

NOBEL PRIZE FOR CHEMISTRY

THE award of a Nobel prize to Sir Robert Robinson, F.R.S., comes as no surprise. It is probably fair to say that he has made more positive contributions to synthetic organic chemistry than any man, living or dead. Where other eminent organic chemists have been content to till one or two fields, he has raised crops from many. His work on the alkaloids, for example, is outstanding and this perhaps is his favourite line; but he is known equally for his achievements with anthocyanine pigments, antimalarial compounds, penicillin, sterols, and sex hormones; while his Faraday lecture at the recent centenary celebrations of the Chemical Society showed that he is equally at home in purely theoretical chemistry. Many good wishes will go to Sir Robert and Lady Robinson, herself a distinguished chemist, on this present recognition of his genius.

was true, had not risen. In recent years, however, there had been advances in prophylaxis, in maternity and child welfare, and in treatment through the introduction of chemotherapy. Why, then, were the figures not greatly reduced? "Because our rotten diet is wiping out all the benefits." As to morbidity, the incidence of infections involving the eyes and skin had risen; convalescents were taking longer to recover; morals were impaired; and tiredness was a ubiquitous symptom. The deterioration was attributable to bad food, and particularly to lack of fat. Dr. Bicknell found it noteworthy that neither of the two principal speakers against the motion were medical men. "To us who are doctors," he concluded, "the nation is ill."

THE MOTION OPPOSED

Sir **Jack Drummond**, F.R.S., submitted that there was no certain evidence that the nation was now less well nourished than in 1938. There was, he said, misunderstanding of the calorie position. For every type of individual the approximate calorie requirements were known; and the weighted average was reckoned by taking all groups together. In the hardest years of the war the weighted average was 2550 calories per day. To provide this, food sufficient to yield 2900 calories per day had been distributed. There was a wastage of about 450 calories, or 9–9$^{1}/_{2}$%, which compared favourably with the 15% wastage before the war. Then, although there had been enough food to yield an overall average of about 3000 calories a day, a third, if not a half, of the population had been underfed. The war had equalised sacrifice; and the Ministry of Food could show that in recent years there had been little difference in calorie intake between the classes.

Additional fat and meat were simply not to be had; for there was a world shortage. Dr. Bicknell had belittled the scientific approach to the distribution of food; but the relief of Europe and the nutrition of Britain in the war had been undertaken with cold-blooded scientific analysis; and it had succeeded. In working-class families the average consumption of every single nutrient was better now than before the war. Certainly the people of Britain were tired out at the end of the war, they had exerted themselves in the war effort more than any Allied, and probably more than any enemy, nation, and it was natural that they should flock to doctors. Vital statistics were the most sensitive indices of health; all had improved since 1940 and none had gone back. There was, moreover, less anæmia in women, less rickets, and less caries; and the growth of children had increased.

The rationing of potatoes was, however, a serious blow. For the nutritionist calories were almost the whole problem; and an essential feature of any rationing scheme was the maintenance of a buffer of energy. With the rationing first of bread and now of potatoes the position was precarious; it was "very grave indeed." However a calorie shortage did not threaten health, provided that there was no major dietary deficiency. Its main effect would be to lower production. Food moving into consumption at the new level of 2700 calories would barely yield 2550 calories to the consumer. The heavy worker and adolescents would go hungry; they would work less and they would lose weight, but their health would not be undermined. Judging by observations in Continental countries, when times improved they would pick up without demonstrable ill health.

SECONDERS

Dr. **Kenneth McFadyean**, supporting the motion, recalled that the Minister of Food had admitted that the nation's diet was to him "a matter of grave concern." When Dr. McFadyean spoke of "grave concern" to the wife of a patient, he was preparing her for the patient's death in another day or two. He dismissed, as untrue, psychological explanations of the prevalent hunger. During the last few years at least one general practitioner had drawn attention to the increasing incidence of hypochromic anæmia; and this was a condition in which only fatigue preceded collapse. In one factory anæmia among the workers had been cured by extra protein; and the observation had been repeated in an establishment for the old when the diet was supplemented. He allowed that children of school age, expectant mothers, miners, and dock workers were well enough fed; "but let some one tell me how many women in the last four years have nursed their babies for more than four weeks." And what about the increasing prevalence of gastro-enteritis? Impetigo, epidermophytosis, sycosis barbæ, and inflammation of the eye were now more common, as also were chronic rheumatic infections and patches of choroid degeneration in the young and otherwise healthy. People were not being starved to death, but their health was suffering. Formerly an army was said to march on its stomach; now people were expected to fly on air, "belching forth exports on an empty stomach."

Mr. **Magnus Pyke**, D.Sc., questioned whether such infections as epidermophytosis could be attributed to nutritional deficiency. Dr. Bicknell, he held, was not justified in dismissing the quantity of sausages, offal, and meat pies as negligible. Since 1941 surveys had shown consumption per head in the home to be steady at 2300 calories. Speakers for the motion had confused average amounts per head with amounts per man; and the 2900 calories suggested before the war as a desirable intake for an unemployed man had been a man value. It was, he said, notoriously difficult to assess nutrition. Perhaps the most sensitive index of undernutrition was the incidence of tuberculosis; mortality from this disease had been falling steadily and was now lower than ever before. Difficulty in getting enough food was greatest for old people; and yet the fall in the death-rate among the over-65's had been greater in the quinquennium up to 1945 than in the previous twenty years. The explanation was a lowered incidence of obesity, alcoholism, diabetes, and high blood-pressure.

The present overall average of 2700 calories was, Dr. Pyke said, compatible with full vigour. Only 72% of this was obtained from the rations, the remainder being derived from unrationed foods in the home, or from restaurant or canteen meals. The food allocated to industrial category-B canteens was capable of yielding 950 calories, while that provided to category-A canteens was capable of yielding 1095 calories. Altogether 179 million meals were served each week, which for 30 million people meant an average of 6 meals weekly.

No-one liked the diet; but a diet that was disliked did not necessarily malnourish the consumer. In Germany there had been complaints of starvation, and the propaganda on dietetic insufficiency was very similar to that in this country. But recent detailed clinical and nutritional surveys in Germany had not substantiated the complaints.

DISCUSSION

Dr. **Nevil Leyton** suggested that the ration of fat was particularly deficient; the allotment was only 30 g. a day. He claimed to be treating cases of œdema due to malnutrition.

Dr. **G. E. Breen** questioned the basis on which Sir Jack Drummond had suggested that a third or a half of the population were underfed before the war. Where did this figure come from? About 50% of infections against units of more than 750 beds. At least the arguments against an indiscriminate increase of size are better appreciated than was the case a few years ago.

Secondly, there is the belief that a vertical design is less exacting in the demands it makes on staff. When the hospital committee sits down to plan in earnest it soon realises that running cost is largely a reflex of the number of staff employed. Requests for increases come in from all quarters; but staff—and especially nursing staff—are not only expensive but are apt to be scarce. Moreover the committee is never long allowed to forget that demands on the time of the medical men must be kept down to the minimum. These considerations seem to emphasise the necessity for a compact design. The wards, it is thought, must not be too far from the kitchens, laboratories, and other central services. The vertical arrangement of the ward units is therefore preferred to the horizontal, even when there are no restrictions on the site, such as dictated the superimposition of the ward units in the case of Middlesex Hospital and of the Westminster.

Thirdly, the steel frame construction has become almost universal where large buildings are concerned. It is cheaper than brick and stone, and lends itself to vertical construction.

It is these three trends that seem likely to take charge and determine the future for us. Is it necessary? Must we say goodbye to the hope that we shall yet see in this country a modern hospital as convincing in its design as many of our older college buildings—and one or two of our older hospitals—and nurses' homes as restful as the medieval quadrangles?

CASE FOR INQUIRY

It seems to be in part a matter of planning, and in part a matter of money. The ward units cannot be spaced out regardless of the central services; but more information is needed on this matter, and exact comparison of the amount of walking involved in some of the most modern examples of vertical design compared with equally modern examples of decentralisation would be of interest. The supposed merits of the vertical construction might prove mythical, or at least exaggerated. In any case it may be that a measure of decentralisation of the catering and other central services would be no bad thing, and here again some detailed data and discussion would be of value. It may too be that it is better to have several nurses' homes rather than one. Even if such decentralisation did prove to carry some disadvantages, it would still be a question whether they would not be far outweighed by some of the points to which attention has been drawn above. Decentralisation does not appeal greatly to those in authority. They—the deans of the medical schools and the matrons of the larger hospitals—have during the war had a good deal of experience of the extreme inconvenience of having part of their hospital located in one place and part in another. It has meant difficulty in control, and a waste of time and energy, and it is only natural that they should lean strongly in the direction of having the whole organisation easily accessible to central control. But it is surely a matter of degree, and if centralisation does militate against our architectural heritage, and all the dignity and peace that it can offer, the sacrifice can surely be too great. May it not in the end have serious repercussions on the availability of staff? If, for example, girls do not like these great buildings and will not choose to nurse in them, what profit is there in all the effort to economise in staff?

OPPORTUNITY FOR BENEFACTORS

In part, however, it may be a matter of money. Hospital construction now demands the fabulous figure of £2000 a bed, perhaps more for the teaching hospital with its special departments. The Minister of Health, it may be said, cannot be expected to have money to spare for such refinements as I have suggested. But even if it be shown that the dictates of economy point all one way, here surely is just the opportunity for the public benefactor to step in and meet the additional cost. Let the Minister fix his figure and make his maximum contribution, and let the voluntary donor, who has in the past willingly supplied money for so much of our hospital construction, provide the extra that is needed to set hospital architecture free from the necessity to conform to the dictates of utility construction. It is difficult to believe that, if the case were properly put and the need for a breakaway from the Continental and American conceptions adequately grasped, there would be any lack of response from those who have the means.

OUR PRESENT DIET

A DEBATE AT THE HUNTERIAN SOCIETY

THE Hunterian Society met last Monday, with Mr. ALEXANDER ROCHE, the president, in the chair, to debate the motion: That Our Present Diet is Undermining the Health of the Nation.

THE MOTION PROPOSED

Dr. FRANKLIN BICKNELL said that, to be healthy, a man must have enough food for a full day's work —namely, 3000 calories. This figure had been agreed by the British Medical Association in 1932 and by the Ministry of Health in 1933; and the League of Nations had set the total even higher. Dr. Edith Summerskill, parliamentary secretary to the Ministry of Food, had stated in the House of Commons that all rations and pointed foods yielded 1530 calories a day. To the total from rationed foods must now be added 139 calories per day from potatoes, which were being distributed on a basis of 3 lb. per week. The new total was thus *1669 calories.*

The gap might be bridged with unrationed foods or with meals eaten outside the home. Unrationed foods consisted principally of offal, meat pies, sausages, fish, and vegetables. The first three were so scarce that they virtually did not enter into the reckoning. If fish were eaten each day, this would yield 200 calories, and vegetables a further 40 calories. The grand total was now 1909 calories. The Ministry of Food in its latest survey had found the average consumption to be 2287 calories; but this was before the reduction in the rations of cheese and sugar, and before the introduction of potato rationing; and allowing for these new restrictions the adjusted figure was 2121 calories. It was quite impossible, said Dr. Bicknell, to close the gap by restaurant meals; restaurants provided altogether only $1^{1}/_{4}$ main meals and $2^{1}/_{2}$ snack meals each week.

There had been cuts in the priority allocations; this must signify either that the priority groups had previously been guzzling at the expense of the remainder, or else that they were now undernourished. The housewife, it was true, needed less food than some other workers; but she had no chance to eat out and thus got no variety in food. It was nonsense to suggest that she ate the "redundant rations" of her children.

No-one knew what food was consumed before the war; and a more relevant question was what was regarded before the war as a satisfactory diet.

If, as he believed, the nation was undernourished, why were there no frank signs of malnutrition? Weight, he suggested, was maintained because the body conserved itself by allowing less work to be done. Mortality-rates, true, had not risen. In recent years, however, had been advances in prophylaxis, in maternity child welfare, and in treatment through the intro-duction of chemotherapy. Why, then, were the figures greatly reduced ? " Because our rotten diet is wiping all the benefits." As to morbidity, the incidence infections involving the eyes and skin had risen ; ents were taking longer to recover ; morals impaired ; and tiredness was a ubiquitous symptom. deterioration was attributable to bad food, and ularly to lack of fat. Dr. Bicknell found it note-ly that neither of the two principal speakers against motion were medical men. " To us who are doctors," concluded, " the nation is ill."

THE MOTION OPPOSED

Sir Jack Drummond, F.R.S., submitted that there no certain evidence that the nation was now less nourished than in 1938. There was, he said, misunderstanding of the calorie position. For every type of idual the approximate calorie requirements were n; and the weighted average was reckoned by all groups together. In the hardest years of the the weighted average was 2550 calories per day. provide this, food sufficient to yield 2900 calories day had been distributed. There was a wastage of 450 calories, or 9–9½%, which compared favourably the 15% wastage before the war. Then, although had been enough food to yield an overall average about 3000 calories a day, a third, if not a half, of the lation had been underfed. The war had equalised ifice ; and the Ministry of Food could show that recent years there had been little difference in calorie ke between the classes.

Additional fat and meat were simply not to be had ; there was a world shortage. Dr. Bicknell had belittled scientific approach to the distribution of food ; the relief of Europe and the nutrition of Britain the war had been undertaken with cold-blooded ntific analysis ; and it had succeeded. In working-families the average consumption of every single ient was better now than before the war. Certainly people of Britain were tired out at the end of the ; they had exerted themselves in the war effort re than any Allied, and probably more than any ny, nation, and it was natural that they should flock doctors. Vital statistics were the most sensitive ices of health ; all had improved since 1940 and none gone back. There was, moreover, less anæmia women, less rickets, and less caries ; and the growth children had increased.

The rationing of potatoes was, however, a serious blow. the nutritionist calories were almost the whole lem ; and an essential feature of any rationing scheme the maintenance of a buffer of energy. With the ning first of bread and now of potatoes the position precarious ; it was " very grave indeed." However calorie shortage did not threaten health, provided there was no major dietary deficiency. Its main would be to lower production. Food moving consumption at the new level of 2700 calories uld barely yield 2550 calories to the consumer. The worker and adolescents would go hungry ; they ld work less and they would lose weight, but their th would not be undermined. Judging by observa-s in Continental countries, when times improved would pick up without demonstrable ill health.

SECONDERS

Dr. **Kenneth McFadyean**, supporting the motion, d that the Minister of Food had admitted that nation's diet was to him " a matter of grave concern." When Dr. McFadyean spoke of " grave concern " to the wife of a patient, he was preparing her for the patient's death in another day or two. He dismissed, as untrue, psychological explanations of the prevalent hunger. During the last few years at least one general practitioner had drawn attention to the increasing incidence of hypochromic anæmia ; and this was a condition in which only fatigue preceded collapse. In one factory anæmia among the workers had been cured by extra protein ; and the observation had been repeated in an establishment for the old when the diet was supplemented. He allowed that children of school age, expectant mothers, miners, and dock workers were well enough fed ; " but let some one tell me how many women in the last four years have nursed their babies for more than four weeks." And what about the increasing prevalence of gastro-enteritis ? Impetigo, epidermophytosis, sycosis barbæ, and *inflammation* of the eye were now more common, as also were chronic rheumatic infections and patches of choroid degeneration in the young and otherwise healthy. People were not being starved to death, but their health was suffering. Formerly an army was said to march on its stomach ; now people were expected to fly on air, " belching forth exports on an empty stomach."

Mr. **Magnus Pyke**, D.Sc., questioned whether such infections as epidermophytosis could be attributed to nutritional deficiency. Dr. Bicknell, he held, was not justified in dismissing the quantity of sausages, offal, and meat pies as negligible. Since 1941 surveys had shown consumption per head in the home to be steady at 2300 calories. Speakers for the motion had confused average amounts per head with amounts per man : and the 2900 calories suggested before the war as a desirable intake for an unemployed man had been a man value. It was, he said, notoriously difficult to assess nutrition. Perhaps the most sensitive index of undernutrition was the incidence of *tuberculosis* ; *mortality from this disease had been falling steadily and was now lower* than ever before. Difficulty in getting enough food was greatest for old people : and yet the fall in the death-rate among the over-65's had been greater in the quinquennium up to 1945 than in the previous twenty years. The explanation was a lowered incidence of obesity, alcoholism, diabetes, and high blood-pressure.

The present overall average of 2700 calories was, Dr. Pyke said, compatible with full vigour. Only 72% of this was obtained from the rations, the remainder being derived from unrationed foods in the home, or from restaurant or canteen meals. The food allocated to industrial category-B canteens was capable of yielding 950 calories, while that provided to category-A canteens was capable of yielding 1095 calories. Altogether 179 million meals were served each week, which for 30 million people meant an average of 6 meals weekly.

No-one liked the diet ; but a diet that was disliked did not necessarily malnourish the consumer. In Germany there had been complaints of starvation, and the propaganda on dietetic insufficiency was very similar to that in this country. But recent detailed clinical and nutritional surveys in Germany had not substantiated the complaints.

DISCUSSION

Dr. **Nevil Leyton** suggested that the ration of fat was particularly deficient ; the allotment was only 30 g. a day. He claimed to be treating cases of œdema due to malnutrition.

Dr. **G. E. Breen** questioned the basis on which Sir Jack Drummond had suggested that a third or a half of the population were underfed before the war. Where did this figure come from ? About 50% of infections had become controllable in the last ten years; yet this improvement was not reflected in returns. If the Government was unable to obtain the necessary amount of food, it should frankly say so. Dr. Breen charged the professional nutritionist with arrogance; people were not machines, and on a given meal one man would do twice as much work as another.

A PRACTITIONER interjected an appeal for the housewife, who, she said, was tired and haggard because she was feeding the rest of the household on her own rations.

Mr. A. DICKSON WRIGHT had found no signs of malnutrition. Arguments for the motion had been flimsy; it was nonsense to ascribe such infections as epidermophytosis to undernourishment, and the reason why mothers did not feed their children was that they did not want to. So long as the nation continued to spend large sums on the purchase overseas of tobacco and alcohol it should not complain that food was insufficient.

Sir JACK DRUMMOND held that no concrete facts had been produced in support of the claim that the country was undernourished. He recalled that in 1940, when it was announced that calcium was to be added to flour, many doctors, some of them distinguished, immediately wrote and continued for months to write, complaining that this addition was causing illness. Yet actually, owing to supply difficulties calcium was not added until eighteen months later, by which time all complaints had ceased, never to be resumed.

When the motion was put to the house, the Ayes outnumbered the Noes by about three to one.

MEDICINE AND RELIGION

A SERMON TO DOCTORS

IN the course of his sermon at the annual service of the Society of Apothecaries of London on Oct. 28, the Rev. M. F. FOXELL, chaplain to the society, said:

Mankind is not divided into two or even three sections—clergy, laity, doctors. To every one of us there is a span of life. Clergy and doctors are mortal like the rest of mankind. We practise our professions as long as we are able and eventually the end comes. The clergy are prone to temptation and the doctors have their illnesses—and vice versa. And at the last there is the fact of physical death.

And what is the meaning and significance of it all? I do not suppose that the study of thanatology deals with that kind of question. It is a question that is shirked by many. "We do not know," it is said. With many that leads to "We do not care," or "What's the use of troubling about it?" That there is one event unto all surely does not minimise the importance of that event. If we are content to take no more than a physical and materialistic view, not only of the universe but also of life in its highest manifestations, religion can have no place. But such a view ignores a great deal of evidence or waves it on one side by the merely arbitrary method of identifying religion with superstition. Neither of these ways is scientific. . . .

The crux of the whole matter rests ultimately on the belief in the nature of man. As a biological specimen he serves as an amazingly large field for knowledge and research: as a unit of social life he may be but a pawn in the hands of politicians. But the Christian view sees man as an immortal soul; and the Christian way of life includes within its range both his physical and social well-being, but subordinates these to his eternal welfare, in the same relation as time stands to eternity. . . .

There is some confusion of thought in making a scientific and analytical approach to a subject that requires other criteria. There are values that cannot be established by scientific method. This is obviously true of the arts. The truth of Christianity lies outside the limited realm of exact science. Its truth is moral, even æsthetic and eternal. There is a borderland between the two regions, but to make that an impassable barrier and to deny the existence of another kingdom because there are difficulties in passing from one to the other is a grave mistake. And it must be borne in mind that theology is not religion, any more than a study of ments and composition is art. Religion is a faith an consequent directing of life. It does not claim to solve ov mystery: it sets forth a well-established theory of life, te full account of the whole man, and relates him to God. Acc ing to the belief in the nature of God, so is man given a p in the eternal realm.

In all this we are on the threshold of many and g problems. The mind delights in problems; we even inv games and puzzles to exercise our intellectual ingenuity. If Christianity is merely regarded as a problem it is missing purpose. We have to make up our minds about it. The m phor is an exact one, and one element in the making must faith. It is my commission to commend the Christian fa However much it can be discussed and debated by its adher and its opponents, we need a return from the complicati resulting from all the knowledge, all the inventions, and the turmoil of civilisation to a simple faith. The sophistica person may smile or scoff at such a notion. Look, he says the universe opened up by telescopic view, look at it as through the microscope, and then can we still be sim minded? We certainly can be made to feel humble, un the advance in knowledge misleads men to a vulgar prid human achievement: or we may be inclined to feel humilia to such a degree as to judge ourselves of no account. But this is too elaborate, and we do not see the wood for the tr or rather, we do not see the sky for the trees.

The Christian is not an obscurantist, but he is aware of element in life that all these observable things may obsc unless he looks with the eye of faith. . . . The subject of Christian religion should not be approached from belo from all the accumulated knowledge of material things, wit vain attempt to find God from scientific evidence; but rat it should be approached from the highest values we kn the noblest characteristics, the best aspirations, the spirit experiences, whether our own or of the saints, and above as these are revealed in the person of our Lord Jesus Christ

Public Health

Poliomyelitis and Polioencephalitis

IN the week ended Nov. 8, 198 cases of poliomyel and 12 cases of polioencephalitis were notified, compa with 221 and 22 in the previous week. The smalln of the fall bears out the suggestion in our last issue th the incidence is likely to remain relatively high for so time. The rate of decline has been fairly consistent the last three weeks, and if it remained the same the rest of the year there would still be about 1 notifications per week at the end of December.

Infectious Disease in England and Wales

WEEK ENDED NOV. 8

Notifications.—Smallpox, 0; scarlet fever, 173 whooping-cough, 1072; diphtheria, 219; paratypho 6; typhoid, 9; measles (excluding rubella), 217 pneumonia (primary or influenzal), 571; cerebrospi fever, 30; poliomyelitis, 198: polioencephalitis, 1 encephalitis lethargica, 1; dysentery, 105; puerpe pyrexia, 107; ophthalmia neonatorum, 54. No ca of cholera, plague, or typhus was notified during t week.

Deaths.—In 126 great towns there were no deat from scarlet fever, 1 (0) from enteric fever, 1 (0) fro measles, 1 (1) from whooping-cough, 5 (1) from dip theria, 61 (3) from diarrhœa and enteritis under two yea and 14 (2) from influenza. The figures in parentheses a those for London itself.

The number of stillbirths notified during the week w 186 (corresponding to a rate of 23 per thousand tot births), including 29 in London.

DURING the June quarter 27,546 new donors joined t National Blood Transfusion Service—twice as many as in t first quarter—and blood was given by 66,557 donors. The are now about 350,000 donors on the panel. To provide f further increases in the demands for blood and plasma and t ensure that donors are not asked to give blood more ofte than once every six months, some 168,000 new voluntee are required in England and Wales.

In England Now

A Running Commentary by Peripatetic Correspondents

It is a popular urban fallacy that we country-dwellers ow all the potatoes we need. In fact few cottagers ve room in their gardens or allotments for more than a ek or two's supply, while we "gentry," with gardens half an acre or so, can get no help (even if we could rd a man at £1 a day) and are doing well if we supply selves with other vegetables and fruit. Economically s unsound to grow main-crop potatoes in a small rden; the cost of manure, seed, and labour con- lerably exceeds the value of the crop. Even Bill up the ad, who grew 5 tons this year in what used to be his t orchard, found that what he got for them only paid the seed and labour, so he was down the cost of the nure.

In this part of the country, which being picturesque ntains an undue number of large hotels, there are omy forecasts of a black market in potatoes. In the tic spell last winter, they say, the hotel-keepers went und in their cars buying up all the potatoes at 30*s*. a t; certainly there were none in the shops. Our rer, who delivers provisions and gossip three times a ek, prophesies that potatoes will soon disappear from e shop once more. Even if they don't things are going be difficult for us who feed at home this winter—and t includes the children in the holidays. In term-time e boys get their midday meal at school, and they get lb. of potatoes a day in that, so they don't do too dly with their ration of 3 lb. a week and an extra B.U. t they (and their parents) will feel the pinch in the idays, when there are no school meals and no milk-in- ool either.

As our grocer says—it all depends on how many meals u can get in canteens or restaurants; if you can feed ut" all the week your rations will do nicely for the ekend. But that is a truly rural point of view.

* * *

In the United States I found that there was a great mand for some English textbooks which were said be unobtainable because of the paper shortage over re. It is a pity if this notable source of dollars is t being tapped efficiently. There seems to be no ortage of paper in America if one is to judge by the e of the daily and weekly newspapers. The smallest bought was the *Boston Herald* with 24 pages. The *icago Sun* had 48 pages and the Saturday edition the *Chicago Daily News* 24 ordinary pages with 52 re in three special supplements. The most lavish use paper was in the *Chicago Tribune* which I bought Sunday, Oct. 5. This was in ten parts and the sum tal of pages amounted to 220. The whole paper weighed lb. 10 oz., and all this was sold for ten cents, which ould be equal to fivepence but actually is now nearer pence. Anyway 7 oz. of reading matter for a penny nnot be considered dear, though if one read the editor's e-too-friendly comments on England one might vise that opinion.

Peripatetic Correspondence, Letters to the Editor, notations, Leaders, Original Articles—thus your respondent of Nov. 1 digests his LANCET. This is deed a dignified and mature approach (he says himself at he is getting old), worthy of a connoisseur beginning s weekly indulgences. This majestic start however is t maintained, for he then proceeds to tear it up and horror of horrors!—throws it away by Monday. This not the behaviour of an epicure but of a glutton, to be pected perhaps in a gormandiser but never in a gourmet. My own colleagues differ in their approaches to this ekly feast. The senior staff work calmly through, arting with the Diary of the Week, while the recently alified residents use it as a missile or club. Only in at shady half-world of the supernumeraries and gistrars do we give the General Advertiser pride of ace, hopefully copying the details of suitable appointents on the back of an envelope, for not many of us e to our own LANCETS.

I hope this view of the seamy side will not distress erybody.

* * *

Now the basic petrol ration has been withdrawn and our non-professional brethren have laid up their cars again, thoughts turn once more to other means of getting about with the least possible expenditure of energy. So it shouldn't surprise one to find a physiologist[1] investigating the best position for a bicycle seat. Using a stationary cycle, and measuring oxygen consumption with the Douglas bag to estimate the energy output in performing a standard piece of work, he finds there are two optimum seat positions. One is the conventional position, which was developed fairly early in the evolution of the modern bicycle. The other is 63° behind the vertical through the pedal axle and is not far from the position of the seat in a child's pedal car. Provided the saddle has a low back to push against this is (just) the most efficient arrangement of all. It is used with success in the French racing velocar, and towards the end of the war was adopted in the little pedal-buggies in which, sitting side by side, mother and father propelled the family around Paris on a Sunday afternoon.

* * *

If I had a literary flair I should write a sequel to de Quincey's masterpiece, called *Confessions of a Membership Candidate*. The clinical picture, with its delusions and hallucinations, is characteristic. When going to an examination you feel that you have got both the day and the place wrong. You confirm them several times by looking at your notification from the examiners. You are sure your watch is an hour slow and that you will be late. If possible you check your watch and all the clocks in the house by the Greenwich time signal. Nihilistic feelings may be prominent. You wish you could melt away and vanish into the ground, and that the examiner would suffer the same fate. Then, of course, there is the psychosomatic aspect. In Edinburgh the ordeal is concentrated into just a week. I had the feeling that if it had lasted any longer I should have perforated or ended up with ulcerative colitis. However, the situation was not without irony. When I was half-way through, Messrs. Plum and Co. favoured me with a piece of blotting-paper advertising their admirable petroleum emulsion. A noble gesture, I thought, and exquisitely timed; inspired no doubt by the desire to pour oil on troubled waters.

* * *

I have been abstracting a paper in English on streptomycin trials in an Athens sanatorium. The author is enthusiastic about the remarkable improvement shown in the radiograms—so obvious that "the most claiming and difficult reader can be satisfied." But he adds, "if there is still any doubt, we think we can repeat to all who are hesitating the reply: 'An evil and adulterous generation seeketh after a sign and there shall no sign be given to it but the sign of the prophet Jonas.'" I racked my brains to think of the relevance of this quotation. Was it that a cavity was involved both in tuberculosis and in the whale? But it seems that the author merely means that if you, dear reader, won't believe him, others will.

* * *

Speaking as a wife—and there's little opportunity to be anything else in British Guiana—it's not a bad thing to live in a hospital compound. Ours, in one of the farthest corners of the Empire, is furnished with a plentiful supply of coloured labour. You want a stamp? A porter will cycle to the post office. The electric iron has gone funny? The hospital electrician works in sight of the house. A wheel has come off the pram? The engineer is here before you can say scalpel. A picture frame needs mending? The carpenter is more than willing. A toy needs painting? What's the painter for? You want a chicken killed or a lettuce planted? The gardener will spring to action. The car is in a mess? The handyman knows *all* about cars. What with all these and a cook-general, a nannie, a scrubber, and a laundress, and only three in family, there isn't really a lot for me to do, which explains why, after only a year in the colony, I have managed to find time to write this.

Letters to the Editor

COMPENSATION VERSUS RESETTLEMENT

SIR,—Last year there came under my care a middle-aged man who had sustained at his work many and serious injuries. It was early apparent that he would never return to his old employment and the advantages of the Disabled Persons Register were explained to him. He was interested and entirely coöperative. The necessary steps were taken. In due course he made a substantial recovery and arrangements were made for him to go to a Ministry of Labour rehabilitation centre, to be trained for a new job while continuing to receive weekly compensation at the full rate. He was still willing and anxious to be trained.

Now there has been formed an unholy alliance between his trade-union and the employer's insurance company to wreck all the good that has been done. The trade-union, living in the past, has told him that under no circumstance is he to submit to being trained until he has received a lump-sum settlement, for if as the result of his training he achieves employment the lump sum will be smaller than if he hangs around and makes no effort. The insurance company support this view, telling the man the same tale and urging him to accept some figure quickly, because if he gets better the sum will diminish.

All surgeons who deal with industrial accidents welcomed the initiation of the Disabled Persons Register as a big step forward in the resettlement of the injured. The failure of the workmen's lay advisers to appreciate the true value of the scheme and their obstruction to its working seem to me to demand some publicity, for though this is a particularly glaring case it does not stand alone. Men more slightly injured, able and willing to go on working while still under treatment, repeatedly state that their trade-union advises against such a course for fear of jeopardising their compensation.

London, W.1. CECIL FLEMMING.

EARLY RISING AFTER OPERATION

SIR,—I found your leading article on Sept. 20 very interesting. Beginning in 1939, my patients as a rule have been out of bed no later than the second day after peration, and for the past two years on the evening of ration.

comment that patients actually hate it, even
opers have tive words of the enthusiastic surgeon and
Your fact patients have convinced them of its
if the seduc he mea foreign to my experience. Since
his "decoy" study of questioned a number of
feasibility, is quite days to two months
reading the editorial I have they have been
patients, at periods varying from tw had previously
after operation. Without exception conventional
enthusiastic about it, and those who ing. On
been operated and kept in bed for the early
period were loud in their praises of early why
several occasions, through oversight, orders
rising were not written, and patients have asked
they were not being permitted to be out of bed like
other patients they had seen. This showed no fear
dislike of the routine.

Certainly, early rising is foreign to surgical custom, and almost barbarous; but I am sure that once one breaks the spell of tradition, one will never return to prolonged bed rest.

Buffalo, New York.

RENAL CIRCULATION

SIR,—In your account (Nov. 1) of the meeting of the section of experimental medicine of the Royal Society of Medicine on Oct. 21, Dr. Heggie is reported to have stated that by his findings "he had indicated to the workers in Oxford [Trueta, Barclay, Franklin, Daniel, Prichard] that the short circuit they had discovered and demonstrated in vivo was via these juxtamedullary glomeruli."

Neither of us, who opened the discussion, have any recollection of a statement by Dr. Heggie to this effect, and, in point of fact, it is entirely incorrect. As part of the demonstration at the Physiological Society, on June 15, 1946 (reported in the proceedings of the society), we exhibited photographs and photomicrographs of kidneys that "incline us to believe that the by-passi is effected, at least in part, via the vasa recta." demonstrated vasa recta with their loops arising fro glomeruli at the base of the cortex and, at that tim called them basal glomeruli. A preliminary communic tion of this demonstration appeared in THE LANC of Aug. 17, 1946, and Dr. Heggie wrote to THE LANC about this communication on Sept. 21. This was the fi we had heard of his beautiful work on the structure the glomeruli, and it was this work that he demonstrat at the recent meeting at the Royal Society of Medicir

Your reporter states that Dr. Heggie had nam these structures as juxtamedullary glomeruli in 194 but Dr. Heggie did not refer to this at the meetir nor have we seen any reference to this publication. Aft his letter in THE LANCET we forthwith adopted the nar "juxtamedullary" and attributed it to him in our bo (*Studies of the Renal Circulation*, p. 51); but to sugge that Dr. Heggie's work has guided us to our conclusic is entirely contrary to facts.

MALARIA TRANSMITTED BY BLOOD-TRANSFUSION

SIR,—With reference to the article by Dr. Roge (Nov. 8), I would like to put on record the followi case.

In 1943 a woman was admitted from a maternity hospit in Hertfordshire to the Hertford County Hospital with diagnosis of puerperal fever. Swabs and blood-cultu however, proved negative, and it was only after several da that a full blood-count was requested. On doing the differe tial count I found, to my surprise, a number of terti parasites, and subsequently, if my memory serves me we the following history was obtained from the patient.

She felt well before, but had a severe hæmorrhage po partum, for which 3 pints of blood were given. Shortly aft the second transfusion the patient had a rigor. All bottl were pooled blood supplied from a transfusion centre, a identification numbers had been destroyed. The patie had never been abroad, but as there were anopheles in th district and as the donors could not be traced, no defini proof could be obtained for the evidence of transfusi malaria and the case was never published. Prof. S. Bedson, then sector pathologist, informed the Ministry, a I believe it was Dr. Banks who investigated this case furthe

I am not sure whether Dr. Banks's personal con munication to the author of the article does not ref to the above case.

General Hospital and Infirmary,
South Shields.

K. S. RODEN
Pathologist.

COAGULATION FACTORS

SIR,—The letter from Professor Seegers (Nov. 1 raises several important issues which arise more or les directly from the interpretation of the results obtaine by the one-stage and the two-stage methods for dete mining prothrombin. In both methods it was originall assumed that a unitary substance, prothrombin, wa

nverted by thromboplastin and calcium to thrombi
account for the difference of prothrombin activit
ined by the two methods, especially when measurin
tivel in various species, Warner, Brinkhous, an
Sn[1] postulated a variation in the convertibility c
prombin—"an element of species specificity."

Wny discovery that the loss of prothrombi
activi stored human plasma could be corrected b
adding dog or rabbit plasma treated with Al(OH)
it becamarent that a principle hitherto unrecognise
was alsontial for the formation of thrombin. A
no time aropose that there were two prothrombins
but I poed that prothrombin was a comple
composed oral components. Originally I called th
principle whsappears on storage "component A"
but later st me to re-designate it as the "labil
factor"[3] anpply the term "component A" t

---

1. Warner, E. khous, K. M., Smith, H. P. *Proc. Soc exp. Biol.*, N, 40, 197.
2. Quick, A. J. *Physiol.* 1943, 140, 212.
3. Quick, A. J. Sept. 13, p. 379; *Amer. J. Physiol.* (i the press).

the principle that is deficient in one type of congenital hypoprothrombinæmia which I recently described.[3] The term "component B" remains reserved for the factor which is diminished in dicoumarol poisoning and in the last type of congenital hypoprothrombinæmia which I reported.[4] Terms such as "accelerator" were intentionally avoided to prevent confusion with thromboplastin. The concentration of the labile factor varies greatly in different species: it is abundant in dog blood and low in human blood. It appears likely that it was this factor that was lacking in the patient of Rhoads and Fitz-Hugh,[5] the first reported case of idiopathic hypoprothrombinæmia, and also in Owren's[6] case (although it is for Dr. Owren to make the final decision).

The one-stage method, by estimating the composite prothrombin activity of blood. has become increasingly valuable clinically and has in addition yielded much scientific information. The two-stage method is now employed relatively seldom for clinical purposes because it is rather complicated technically and because it yields perplexing results in certain conditions—as for example in early infancy.[7] Dr. Seegers's expression "the more reliable two-stage method for measuring prothrombin activity" must be considered as relative. In his type of investigation with the use of purified reagents it has yielded valuable results, and every worker in the field is appreciative of Dr. Seegers's contributions. Unfortunately the problem of hæmostatic dysfunction cannot yet be bodily transferred to the test-tube. Much information must still be sought by direct study of blood. and for this purpose the one-stage method has proved its value by the test of time.

At present both approaches are still necessary, and the two types of effort should complement each other rather than antagonise. Ultimately it will likely be found that much of the present confusion is one of terminology rather than of basic facts.

ARMAND J. QUICK.

THE BARBITURATES

SIR,—Your leading article of Oct. 18 was most timely, and will cause many to reflect. In your issue of the following week Dr. G. Thurston wrote protesting that "it would be impossible for a busy doctor to see, say, every week all his patients who took phenobarbitone." May I suggest a simpler mode of caution? State upon the prescription that the supplies are to be issued weekly to the patient.

Hasterworth, Gloucester.
S. P. VENABLES.

"JUGGED HAIR"

SIR,—On the cover of the July 27, 1946, *British Medical Journal* appeared in large print "Vinesthene Anæsthesia for Repair of Hair-lip and Cleft Palate." I expected to see some apology for this mis-spelling or at least a letter from some wag cleverly pulling the leg of the editor who had allowed it to pass him. Either it went unnoticed or I overlooked reference to it in subsequent issues of the journal.

In the Oct. 18 *Lancet*, p. 588, in an annotation I read: ". . . since the feeding of a child with a double hair-lip is at best tedious, . . ." In the three issues since that date I have seen no correction of this mis-spelling.

It is perhaps to be expected that a surgeon who receives a great many letters about this condition from parents and general practitioners should have come across this mistake frequently, but it seems odd that the editors of our two leading medical journals should have allowed it to pass. For twenty years or more I have refused to use the term at all: and I and those who have worked with me have adopted the terminology "cleft lip" first suggested, I believe, by Ritchie, of St. Paul, Minnesota—more descriptive, less inapt and less likely to lead to incorrect spelling.

Nuffield Department of Plastic Surgery, Churchill Hospital, Oxford.
T. POMFRET KILNER.

TEACHING APPOINTMENTS

SIR,—In your leading article (Oct. 25) dealing with Dr. Clark-Kennedy's new textbook you state: "He has concluded that medicine is in serious danger from the dominance of specialism. Increasingly narrow specialists are not the best people to control the teaching of the undergraduate student."

The importance of this is not generally realised. and few seem to appreciate what is happening in most of the teaching schools. Several recently appointed professors of medicine are primarily not clinicians but physiologists or workers in some other branch of research: and this tendency has spread to recent appointments of readers and senior lecturers.

Knowledge of general medicine, clinical experience, ability to lecture, enthusiasm and flare for teaching—these apparently are of little consequence. Research-workers are dominating the teaching schools and obtaining most of the full-time teaching appointments; and research-workers are often bad clinicians and poor teachers. From personal experience and the opinions of interested friends, I know that the teaching of medicine to undergraduates in many schools is of poor quality; and the much-boosted and advertised postgraduate teaching is often worse.
M.R.C.P.

RUPTURE OF THE SPLEEN

SIR,—I should like to call attention to the leucocytosis with relative and absolute decrease of lymphocytes in the case reported by Dr. Druitt (Nov. 1). This condition of the blood is found with traumatic rupture of spleen. according to Bieri,[1] and it is therefore a useful sign in establishing the diagnosis.

Institute for Morbid Anatomy, University of Bratislava, Czechoslovakia.
F. KLEIN.

EFFECT OF BENADRYL ON GASTRIC ACIDITY

SIR,—Mr. Doran's letter of Sept. 27 is an important contribution in that it demonstrates that anti-histamine drugs are probably bad treatment for hyperacidity, and in that it helps to uncover a very significant physiological fact. The conclusion however that his results "throw some doubt on the hypothesis that the ultimate stimulus to the parietal cells is normally histamine" may be challenged.

The position is briefly this. Histamine is widely regarded as the physiological stimulus for acid gastric secretion. Certain drugs have been proved to exert an anti-histamine action, and from quantitative studies it is concluded that this action is in the nature of substrate competition. It was thus natural to attempt to reduce gastric acidity by the administration of these drugs, but these attempts have not only failed but often actually resulted in increased acid gastric secretion. From this paradoxical result Doran concludes that histamine may after all not be the physiological stimulus of acid gastric secretion.

This conclusion overlooks the fact that if histamine were unconcerned with acid gastric secretion the administration of anti-histamine drugs should make no difference either way. Doran's line of thought, followed to its logical end, would lead to the conclusion that histamine is actually an inhibitor of acid secretion—a view which seems untenable in the present state of our knowledge.

Assuming that the histamine theory of acid gastric secretion is correct, we must conclude from the above experiments that the administration of anti-histamine drugs led in these cases to an increased supply of histamine to the gastric mucosa. Now, if we accept the idea that these drugs act by substrate competition, then their administration must, ceteris paribus, lead to an increase of circulating histamine by an equivalent amount, as the drug interferes with the fixation of histamine to the H-sensitive cells. This excess could, however, have no influence on the acid gastric secretion unless the mechanism by which histamine affects the parietal cells of the gastric mucosa is different from that by which it produces its effects in other tissues, and such that it is either less or not at all interfered with by the anti-histamine drugs.

Quick, A. J. *Amer. J. lab. clin. Med.* 1946, 31, 79.
Rhoads, J. E., Fitz-Hugh, T. jun. *Amer. J. med. Sci.* 1941, 202, 662.
Owren, P. A. *Lancet*, 1947, i, 446.
Brinkhous, K. M., Smith, H. P., Warner, E. D. *Amer. J. med. Sci.* 1937, 193, 475.

---

[1] Bieri, J. *Schweiz. med. Wschr.* 1946, p. 1053.

The hypothesis that the action of histamine on the gastric mucosa is different from its action elsewhere seems reasonable because in the stomach it has a specific function to perform, whereas in most other sites its action is general and (with normal amounts in normal individuals) feeble. It is well known that many active metabolites, while they have a feeble general effect, have a pronounced action on special organs; and it must be assumed that in these instances two different mechanisms are at work. Thus, with an even concentration in the blood, gonadotrophic hormones act chiefly on the gonads, gonadal hormones chiefly on the secondary sexual organs, and thyrotrophic hormone chiefly, though not exclusively, on the thyroid gland.

An analysis of the present situation leads to the following conclusions:

1. There is strong evidence that histamine is a physiological stimulus for acid gastric secretion.
2. There is strong evidence that administration of "antihistamine" drugs increases acid gastric secretion.
3. It seems therefore probable that the action of histamine on the gastric mucosa is a specific one—i.e., different from its action on other tissues.
4. This conclusion is in accordance with the known facts about the action of many other active metabolites (hormones, vitamins, enzymes).

Far from throwing doubt on the histamine theory of acid gastric secretion, Doran's results may be evidence in favour of it, indicating as they may a specific reactivity of the gastric mucosa to histamine.

Surgeons' Hall, Edinburgh. ERICH GEIRINGER.

URETHANE IN CHRONIC MYELOID LEUKÆMIA

SIR,—The question whether urethane can prevent relapses in chronic myeloid leukæmia cannot be answered with certainty, though Paterson and her co-workers[1] state that it cannot do so. Equally, it is still uncertain whether severe damage to the hæmopoietic tissues is attributable to urethane, though Paterson et al. mention a case in which there were signs of aplasia, perhaps due to urethane. Davidson[2] refers to toxic effects but does not specify their nature.

No report has been published of chronic myeloid leukæmia treated continuously for long periods with urethane; and for this reason the present cases are placed on record.

CASE 1.—A woman, aged 26, had been diagnosed as having chronic myeloid leukæmia in 1942, but was free from symptoms until about August, 1945.

When I first saw her in October, 1945, she complained of bouts of sickness, fatigue, occasional fever, and increasing size of her waist. Her spleen extended below the umbilicus, and there was extreme tenderness on pressure over the lower part of the sternum. The leucocyte-count was 200,000 per c.mm. (with the usual differential count of chronic myeloid leukæmia) and there were 340,000 platelets per c.mm.

She was given X-ray treatment by Dr. Russell Reynolds, and by the end of December, 1945, the number of leucocytes had fallen to 14,200 per c.mm., with few myelocytes present.

By April, 1946, the leucocyte-count had again risen to 71,000 per c.mm., and the spleen, which had almost retired to the costal margin, was again below the umbilicus. The patient again had X-ray treatment and improved, but on Aug. 16, 1946, the leucocyte-count was 78,000 per c.mm., the lower sternum was tender, and the spleen reached the umbilicus.

She was now given enteric-coated capsules of urethane (Martindale) 0·5 g. thrice daily. A month later the spleen was half-way between the costal margin and the navel, the sternum was not tender, and the leucocyte-count was 46,000 per c.mm.

The patient continued to take urethane, and in January, 1947, the leucocyte-count was 6250 per c.mm. Urethane was continued in spite of the diminished white-cell count, and shortly afterwards the patient found that she was pregnant. Even so, the same dose of urethane was continued, and in May, 1947, when the leucocyte-count had risen to 21,500 per c.mm., the dose was increased to four capsules (2 g.) daily. This was continued throughout the pregnancy until, Aug. 30, Mr. Leslie Williams performed a cæsarean section.

The baby appeared perfectly healthy, its neonatal blo picture was within normal limits, and it has gained weig steadily during the first month of life. The mother can fe the child and appears to be in excellent health. The brea milk contained less than 15 mg. of urethane per 100 ml.

Urethane was only stopped for a few days after the operati during a slight urinary infection, but three days after t birth the leucocyte-count was only 18,000 per c.mm.

The mother and child remain in good health (a month af the cæsarean section) and the total amount of urethane tak up to that time was nearly 900 g.

No signs of toxicity have been noted, and as yet there no signs of a relapse, though the blood picture is, of cour not normal.

CASE 2.—A woman of 41, with a total leucocyte-count 695,000 per c.mm., has had 300 g. of urethane in five mont with a resultant fall in the number of leucocytes to 104,0 per c.mm. Treatment is being continued.

CASE 3.—A woman of 67, with a spleen that would longer respond to radiotherapy, has had 400 g. of urethа in nine months; and, as a result, the spleen has retir behind the costal margin.

My results in cases of chronic lymphatic leukæmia far less satisfactory, and in acute leukæmia urethane h proved to be useless.

It seems possible that the toxic effects attributed urethane may be due to its use as a method of produci the same sort of rapid improvement in the blood pictu as can be obtained by radiotherapy. My experience the cited cases (and in others) is that a moderate dc (in enteric-coated capsules to avoid nausea) produces more gradual but equally spectacular improvement, a that a maintenance dose can be given to avoid relaps If only in the last respect, urethane is more useful th radiotherapy, which has to be administered episodicall

Case 1 is not the only recorded example of a success pregnancy in a leukæmic woman, but it is the only o in which urethane has been given throughout. He again, urethane has a great advantage over X rays, whi cannot safely be given during pregnancy for fear damage to the child, whereas urethane is apparent *innocuous to the fœtus.*

THE HEALTH OF AUTHORS

SIR,—In his delightful and refreshing lecture (Nov. 1 Mr. Harold Nicolson refers to A. E. Housman as displayi "plodding assiduity." This I find surprising, for in h preface to the first edition of *Last Poems* Housm writes: "I publish these poems, few though they a because it is not likely that I shall ever be impelled write much more. *I can no longer expect to be revisit* by the continuous excitement under which in the ear months of 1895 I wrote the greater part of my oth book, nor indeed could I well sustain it if it came. Surely these words suggest that with Housman, to inspiration was an impulse.

London, N.14. ARNOLD BLOOM.

ESTIMATION OF RENAL ACTIVITY

SIR,—It seems that some of the statements in tl article by Dr. Greiner and Professor Podhradszky, o Oct. 4, require comment.

They stated that "reduction in urinary flow is du to changes occurring simultaneously in glomerular an tubular functions, the latter, owing to their large extent, being more important." On referring to fig. we find that the tubular reabsorption *decreases*, durin the thirsting phase, and that the reduction in urine flo is mainly due to a reduction of filtration-rate. Th values from fig. 3 (*a*) are: glomerular filtration-rat 160, 145, 100, 128 c.cm. per min.; urine flow 10, 2·4 0·5, 3·7 c.cm. per min.; and tubular reabsorption c water 150, 142·6, 99·5, 124·3 c.cm. per min.

It seems that the chloride clearance is used as a estimate of tubular function. Now when the tubula reabsorption is large, less work need be performed, i withdrawing a given amount of chloride from the tubule than when the water reabsorption is less. This is obviou since the reabsorbate in the former case will be les trated than in the latter, and it is difficult to see a value like chloride clearance can act as an indication "increased tubular function." It is more rational regard concentrating power as an index. Where the urinary concentration of creatinine, P the concentration of creatinine, and V the minute-me of urine, the clearance, represented by UV/P, remain the same although U rises.

this connexion it is interesting that Barcley et al.[1] suggested that the concentration ratio of creatinine be used as an indication of renal function.

Department of Anatomy,
dical School, Birmingham, 15.

DAVID F. COLE.

INFECTION FROM SPINAL ANÆSTHETIC

R,—It appears that almost all the cases of infection spinal anæsthesia have been traced to con- tion of the so-called sterile water used for washing the needles and syringes. May one who, although a professional anæsthetist, has given many hundreds pinal anæsthetics, without incident so far, offer a of advice?

ver use any "sterile water": there is always too h anæsthetic solution in the ampoule and this is ys sterile. I attach the spinal needle to the syringe draw up a little of the anæsthetic; this washes ugh the needle and can be shaken about in the l of the syringe. Apart from the mechanical -out, the introduction of this small amount of hetic will use up anything present in the needle ringe which might cause precipitation of the anæs- sing agent; in fact, this was my reason for adopting a technique in the days when cocaine products, h are more easily affected in this way, were in more on use.

is simple technique avoids the need for using sterile r which, in my opinion, should always be regarded suspicion.

ternity Hospital, Kingshill, Swindon.

GUY ROWORTH.

DEPERSONALISATION SYNDROME

R,—The article of Nov. 15 by Dr. Shorvon is of importance. Psychiatrists and psychotherapists benefit by the careful study of the cases reported .

my mind, the very features of the complaints in patients distinguish them from psychoneurotics are fit for analytical therapy. May I say that, apart the early "enthusiastic" days of my practice, ould have recognised these cases as unlikely to to the most skilful analytical therapy. Case 5 aps might have benefited by such treatment after first attack, in having had less proneness to react depersonalisation, even though one ought not to be about this. But in general it is unjustifiable to d much time and money on a prolonged experiment sycho-analysis in cases of the type referred to in von's publication. The rare cases of depersonalisation h did improve by psycho-analysis (I know of only showed a different character and development.

us, however, does not imply that this syndrome is ys quasi-psychotic and not a disturbance of psycho- tive processes. The few cases which yielded to ether action do suggest that the feeling of unreality may be re psychoneurotic manifestation, even though not e type that reacts to the ordinary analytical approach.

don, W.1.

S. LOWY.

LANCETS ON LOAN

of. K. Thomas, dean of the medical faculty of the Univer- of Erlangen, writes to say that for some time past he een receiving copies of THE LANCET regularly. Professor nas has been unable to trace where the packets come , but he and the other members of the faculty, with n he shares them, would like to thank the unknown donor. ugh many periodicals are available in the American ry at Erlangen they cannot be taken away on loan, and, rofessor Thomas remarks, "Wer von uns hat schon iber die Zeit sich in die Bibliothek zu setzen?" He and colleagues are therefore all the more grateful to the rmous LANCET-lender.

Parliament

FROM THE PRESS GALLERY

Medical Practitioners and Pharmacists Bill

IN moving the second reading of this Bill in the Upper House on Nov. 11, Lord HENDERSON said its object was to dispose finally of the war-time problems associated with the admission to the British Medical Register of doctors not possessing British qualifications. After briefly describing its main provisions[1] he added that when temporary registration ceased there were about 3500 names on the temporary register. This figure included many American and Canadian doctors, and of the others —Germans, Austrians, Poles, and Czechs—many had returned to their own countries. It was estimated that not more than 1500–2000, including the Polish doctors who had come to this country under the Polish resettlement scheme, would avail themselves of the Bill.

The Bill also provided for the registration—in the first instance on a provisional basis—of certain doctors who are not on the temporary register. This power, Lord Henderson emphasised, was limited to doctors who were in this country when the Bill was introduced. Neither in this Bill nor in our war-time measures, he thought, had we treated foreign doctors ungenerously, but we must put some limit on the relaxation of ordinary procedure. Permanent modification of the present law—which makes the registration of foreign doctors dependent on reciprocity—would be beyond the scope of the Bill.

Only clause 8 in part I of the Bill, therefore, would be permanent. Its intention was to regularise the position of doctors visiting this country for a limited period, either as teachers or as postgraduate students. Many of these visitors were not eligible for registration under the Act of 1886, and technically it was a professional offence for a registered practitioner to coöperate in professional work with an unregistered person. These doctors were at present also unable to give statutory certificates or to possess or supply dangerous drugs. It was true that in the past no legal difficulties had arisen, but the risk had been there, and the Government thought it should be removed, especially as in the near future hospitals would become a State responsibility. Registration under this provision would be temporary and would only be given for the duration of and in respect of specific appointments. The Bill would give the General Medical Council the necessary powers in regard to these doctors. The council, he added, were the guardians of the standards of medical education in this country and we could safely leave to them the task, which might not prove easy, of assessing the value of the great variety of medical diplomas held by applicants under the Bill.

Though Lord LLEWELLIN welcomed the Bill, "for we are not overflush with doctors at present," he stressed the medical profession's satisfaction that the Government, since the Bill was first introduced, had limited eligibility for registration to doctors already in this country on Aug. 4, 1947. Lord HARLECH supported the Bill because it sought to break down the idea that all the doctors from one country should be recognised and allowed to practise here and that none of the doctors from other countries should be recognised. Recognition, he held, ought to be personal and should depend on whether a man was properly qualified. He hoped to see the day come when there would be more interchange of medical experience, medical research-workers, and medical practice between all the countries in the world.

QUESTION TIME

How Many Calories?

Major E. A. H. LEGGE-BOURKE asked the Minister of Food how the daily calorie content of the weekly minimum amount of food regarded as necessary for an unemployed man, as decided by the Ministry of Health in coöperation with the British Medical Association in 1933, compared with that of the present ration after the reductions recently announced by the Government.—Mr. J. STRACHEY replied: The calorie value of the no. 2 diet suggested for an adult man by the British Medical Association in 1933 was 3386 calories daily. As announced by the Minister of Economic Affairs, the recent reduction in distribution will result in an estimated average daily calorie intake of just below 2700 per head for the whole population. Major LEGGE-BOURKE: Is the Minister aware that his reply will cause considerable concern in the country, and can he say whether the figure of 2700 calories quoted by the Minister of Economic Affairs took into consideration the recent cut in potatoes?—Mr. STRACHEY: Yes, sir; it did take into consideration the rationing of potatoes. I cannot agree that there was a ration figure for the unemployed before the war, but I entirely agree that the level of calories which I have just quoted is a matter of grave concern.

---

[1] See *Lancet*, Nov. 8, p. 703.

Mr. SOMERVILLE HASTINGS: Is it not a fact that many people engaged in sedentary work are not now taking in 2700 calories a day?—Mr. STRACHEY: Yes, sir. The figure of 2700 is the average figure. There are many sections of the population getting very much more; therefore there are many who are getting much less. Mr. J. S. C. REID: How many calories are represented by the cut caused by potato rationing?—Mr. STRACHEY: Seventy.

Replying to a further question, Mr. Strachey gave the following calorie values for the rationed foods (not including eggs or pointed foods) of a normal adult:

Meat ..	.. 117	Sugar ..	.. 123
Bacon ..	.. 15	Bread ..	.. 648
Cheese ..	.. 33	Milk ..	.. 102
Butter ..	.. 61	Preserves	.. 41
Margarine	.. 124		
Lard ..	.. 36		1300

Calories for Industrial Workers

Lieut.-Colonel U. CORBETT asked the Minister what was the calorie value of the rations available to the following categories of workers taking account of basic rations, extra rations, and canteen rations: miners, workers in factories having canteens, farm workers, and other working men.—Dr. E. SUMMERSKILL replied: Assuming that a worker takes five main meals and five hot beverages a week at his canteen, the average calorie value of his basic rations, including points and sweets and the rations provided through the canteen, would be 3370 calories a head daily for a miner, and 2530–2630 for an industrial worker, depending on the type of canteen available. Agricultural workers' rations provide 2600 calories a head daily. Other workers get amounts which depend on the nature of their work, and the provision of canteens.

Rations for Hospital Patients

Mr. H. W. BUTCHER asked the Minister whether the patients in hospitals and nursing-homes would suffer the recently announced cut in civilian rations.—Mr. STRACHEY replied: Residents in hospitals and nursing-homes are entitled to the same rations as the domestic consumer. Additional foods considered necessary on medical grounds may be obtained in the same way as for people suffering from similar complaints at home. Special cuts of 15% or 17½% in the allowances of various rationed and controlled goods to certain catering establishments made because of the crisis were not applied to residents in catering establishments or anyone in institutions.—Mr. BUTCHER: While bearing in mind the fact that persons in these institutions have no access to public canteens, or other methods of feeding out, is the Minister really satisfied that the ration these people will receive will be adequate to restore them to good health?—Mr. STRACHEY: That was why we did not apply the recent catering establishment cut to these places.

Health and Nutrition Surveys

Mr. BUTCHER asked the Minister whether, in view of the reduced rations, he would arrange for frequent surveys of the health and nutrition of the civilian population and for the publications of the reports of such surveys.—Mr. STRACHEY replied: Surveys of health are the responsibility of the Ministry of Health, but the Ministry of Food has been carrying out a monthly survey of food consumed in the home since 1941, and will continue to do so. A report on the survey results from 1941 to 1946 is now being prepared for publication. Ad-hoc surveys are also arranged to investigate current problems and difficulties.

National Health Service

Sir E. GRAHAM-LITTLE asked the Minister of Health if he would now give an estimate of the number of general practitioners and specialists, respectively, which would be req to warrant putting into operation the National Health Se Act, 1946, now proposed to take place in July, 1948; and measures had been taken to provide additional ho accommodation, health centres, and other buildings req to carry out the provisions of the Act.—Mr. A. BEVAN rep The National Health Service will be brought into oper with the resources available at the appointed day. T resources will be extended as circumstances permit.

Obituary

WALTER ROWLEY BRISTOW

M.B. LOND., F.R.C.S.

Rowley Bristow's influence as orthopædic sur to St. Thomas's Hospital and as orthopædic consul to the Army will long continue through his power leader and teacher of young men.

Born in 1882, the son of Henry Joseph Bristow Bexley, Kent, he began his medical studies St. Thomas's, where he won renown not only as a p winner but as a member of the soccer, lawn-tennis, water-polo teams, and later as a scratch golfer and owner of a series of sporting motor-cars. In 1907 took the Conjoint qualification, and the following year his M.B. After holding house-appointments at the hospital he obtained his surgical fellowship in 1909, and when war broke out in 1914 he was already established in consulting practice as a traumatic surgeon. With the Middlesex Yeomanry he served in Gallipoli and was mentioned in despatches for his work at Suvla Bay. In 1916 he returned to England to work at Shepherd's Bush military hospital with Sir Robert Jones. Here he quickly became Sir Robert Jones's disciple and friend, for they shared the same vigour of bo ability of mind, and generosity of character. After war their association continued, for in 1919 St. Thom set up an orthopædic department with Sir Robert its titular head and Bristow as his active assista When Bristow retired from the staff early this yea tribute in the hospital gazette acclaimed him as fact from the start the real director of this departme "Though he was a loyal and ardent admirer of Rob Jones, he proved no slavish follower of the Liverp school. His organising ability and his happy kn of picking good assistants and getting good work out them soon established the new venture on a sou footing." But his affectionate respect for his old ch continued, and it was appropriately recognised by h election last year to give the Robert Jones lecture the Royal College of Surgeons, when he spoke on injuri of the peripheral nerves. With his work at St. Thoma he combined his surgical directorship of the St. Nichol Hospital for Cripples at Pyrford, to the advantage of bot He was also on the consulting staff of the King Edwa VII Hospital for Officers at Osborne.

When war came again in 1939 Bristow was appoint orthopædic consultant to an E.M.S. area, but in th following year he became orthopædic consultant the Army, and in 1941 he was made consulting surge in orthopædics to the Army, with the rank of brigadie In the course of his duty he flew many thousands miles across the Atlantic and over the Mediterranea and Middle East. He was largely responsible for th establishment of orthopædics as a specialty in th Army, and the Service gained immeasurably from h choice and direction of young surgeons, from who he demanded something of his own whole-hearte efficiency. They gave of their best for the work itse and in loyalty to their leader.

Bristow's colleagues at home trusted him fully, an he was president of the British Orthopædic Associatio in 1937. He was also elected to the orthopædic associa tions of America, France, and Belgium. and last year he was appointed chevalier of the Legion of Honour, and awarded the Croix de Guerre with palm. Of his international relations a Canadian surgeon says: "To see the many visitors from the United States and Canada come to his doorstep, whether mature orthopædic surgeons or not, to wonder, marvel, and then remain to learn, was a never-ending pleasure. Here was a man to warm the cockles of the hardest transatlantic heart, with his straightforwardness, his singleness of purpose, his cutting of the inevitable red tape, his brilliance, and his conciseness of thought and dynamic action. Some of us discovered his kind affection and his pleasure in all things beautiful. Those of us who visited him at his ome, where he fondly and proudly displayed his alpine owers, his herbaceous border, and his fruit and vegetable arden, and talked quietly with him by his fireside, could ppreciate the greatness of the man and the loving-indness in his heart which he hid behind his somewhat ustere and brusque exterior. We, who had the privilege f working with him, have had our moments of difficulties, lways of our own making, and at a later stage have ppreciated his mature advice and wise guidance. No ore will we be affectionately greeted, with the pungent emark that so often went home, by the man with the parkle in his eye, whom we came to love, admire, and spect."

As O. M. P. puts it, Bristow "possessed the happy nack of getting loyal coöperation from all his assistants. utside his professional work he was keen on many rms of sport: above average as a player of ball games, e continued to be a good golfer till a few months before s death; lately his main interest had been in fishing d shooting. He thoroughly enjoyed the social casion and showed both generosity and discrimination his entertainments both at home or in his club. He ved his life to the full and with good courage."

"It is difficult to believe." writes H. P., "that Walter ristow has gone from our midst whilst still at the height his powers. For to his colleagues, his pupils, and his iends—in many different walks of life, all over the world —he seemed invulnerable. We had looked forward to his njoyment of a long Indian summer, in which some of us, both young and old, might have continued to share his radiant spirit. In his genius for friendship, and in the ideal setting of his home and family life, we have lost something which is irrèplaceable. By the death of Walter Bristow, international orthopædic surgery loses one of its outstanding leaders, and we mourn the passing of a master surgeon."

We conclude by quoting part of a tribute from G. R. G.: "My long friendship with Rowley Bristow," he says, "has been to me a source of great happiness, and valued even more because all the time I have been learning from those things he taught by example to all who were with him—to get at the facts, to keep one's feet on the ground, and to master one's methods. It is human to make mistakes, and he was very human, yet probably he made as few mistakes as any man. This, I think, was due to his essential humility, shown by his eagerness to learn from juniors and seniors alike provided they could give their proofs. We shall miss him as a man of outstanding character, with a genius for life and friendship, and above all else a most heartening presence."

Mr. Bristow married in 1910 Florence, only daughter of James White, LL.D, and they had one son and two daughters. He died in London on Nov. 10.

WALTER KING HUNTER

M.D., D.SC., LL.D. GLASG., F.R.F.P.S.

Prof. W. K. Hunter, who died on Nov. 7 at the age of 80, was one of the most distinguished physicians of his generation in Scotland. The active years of his life were spent in the service of Glasgow Royal Infirmary, where he was in turn student, house-physician, and a member of the visiting staff until he retired in 1934. From 1903 until his appointment to the newly instituted Muirhead chair of medicine in 1911, he was lecturer in the practice of medicine at Queen Margaret College.

After leaving the Glasgow Academy, Hunter entered the faculties of science and medicine at the university, graduating B.SC. in 1888 and M.B. in 1890. Seven years later he obtained the degree of M.D., and in 1901 that of D.SC. On his retirement from his chair the university conferred on him the honorary degree of LL.D. A fellow of the Royal Faculty of Physicians and Surgeons, he held various offices in the faculty, including examinerships in medicine for the licence and for the fellowship. In his younger days Hunter was on the staff of the Glasgow Royal Hospital for Sick Children, and it was a great satisfaction to him to serve in later years on the board of governors. He was also for many years consulting physician to Glasgow Royal Mental Hospital. He was one of the foundation members of the Association of Physicians of Great Britain and Ireland, and he also took an active part in the work of the local medical societies, holding various offices, including that of president of the Glasgow Royal Medico-Chirurgical Society.

Hunter's years of postgraduate study on the Continent, when he visited the neurological clinics of the Paris hospitals, laid the foundations of a life-long study of neurological problems which he combined with a keen interest in hæmatology. His work in these two subjects formed the basis of a number of publications, including a small monograph on the anæmias, and he contributed to our columns (1904–06) a series of papers on the action of snake venoms on the nervous system.

"Hunter was not an easy man to know," writes J. N. C. "His rather formal speech and mannerisms tended to give a false impression. Perhaps his most characteristic trait was a horror of overstatement and of flamboyance in speech, behaviour, and dress. What is now called 'shooting a line' was abhorrent to him. But to the man who was interested in learning clinical medicine, his teaching was an inspiration and his equanimity an example. Uncle Walter, as he was called by generations of students, will long be remembered with the late W. R. Jack, John M. Cowan, John McKenzie Anderson, and others happily still with us, who carried on the clinical tradition of the Auld Hoose. One of the secrets of Hunter's happiness was the variety of his interests. He was deeply read in general as well as in medical literature. His appreciation of music, poetry, and painting was founded on a real knowledge of these arts and he was devoted to quiet rural pursuits. All these were elements in the background of a busy life spent in the service of the community."

Births, Marriages, and Deaths

BIRTHS

Bartholomew.—On Nov. 10, at Bath, the wife of Dr. N. I. Bartholomew—a son.

Denny.—On Nov. 11, at Plymouth, the wife of Surgeon Lieut.-Commander G. C. Denny, R.N.—a daughter.

Hargrove.—On Nov. 11, at Wokingham, Berks, the wife of Dr. Peter Hargrove—a son.

Mason.—On Nov. 9, at Aylesbury, the wife of Flight-Lieutenant J. K. Mason, R.A.F.—a son.

Pike.—On Nov. 6, in London, the wife of Dr. Charles Pike—a daughter.

Southern.—On Nov. 10, in London, the wife of Dr. E. M. Southern—a daughter.

MARRIAGES

Gavourin—Thomson.—On Nov. 3, at Guildford. H. S. Gavourin, M.B., lieutenant, R.A.M.C., to "Terry" Thomson.

McCormack—Jones.—On Nov. 13, Robert John Murray McCormack, M.B., to Gwyneth Avarina Jones.

Osmond—McKenzie.—On Nov. 12, at Milford, Surrey, Humphry Fortescue Osmond, M.R.C.S., surgeon lieutenant, R.N., to Amy Edith McKenzie.

Wakelin—Ellis.—On Nov. 12, at Copthorne, Sussex, John Wakelin, M.R.C.S., to Joan Ellis.

DEATHS

Dickinson.—On Nov. 15, at Eastbourne, William Henry Dickinson, M.B. Edin., lieut.-colonel, I.M.S. retd.

Fawcett.—On Nov. 8, at Harrogate, Herbert Fawcett, M.A. Camb., L.S.A., aged 77.

Fraser.—On Nov. 9, at Fittleworth, Sussex, Margaret Helen Fraser, M.B. Lond., aged 75.

Hingston.—On Oct. 14, James Clarence Ledeatt Hingston, M.R.C.S., D.P.H., colonel, R.A.M.C. retd., aged 65.

O'Donnell.—On Nov. 10, at Ledbury, Sir Thomas Joseph O'Donnell, K.C.I.E., C.B., D.S.O., L.R.C.P.I., major-general, A.M.S. retd., aged 89.

Ritchie.—On Nov. 8, at Dunedin, New Zealand, Russell Ian Ritchie, M.B., M.R.C.O.G.

Shea.—On Nov. 12, at Royston, Henry Francis Shea, D.S.O., M.B. Durh., colonel, R.A.M.C. retd., aged 75.

Winder.—On Nov. 12, James Herbert Roche Winder, D.S.O., B.A., M.D. Dubl., lieut.-colonel, R.A.M.C. retd.

Notes and News

PURCHASE-TAX ON DRUGS

THE British Medical Association has sent to the Ministry of Health a strong protest against the increase of purchase-tax on many classes of drugs which is proposed in the Budget. "It is impossible," the association says, "for any doctor with the interests of his patients at heart to view other than with grave concern any measure which increases the cost of sickness, or adds to the anxiety which accompanies illness. Many of the drugs affected by the increase of purchase-tax are in constant use. The association feels bound to point out that a substantial increase in the cost of these medicines is bound to be reflected in increased cost of medical services which will fall most heavily on the chronic sick, to whom perhaps more than any other sections of the community, this additional burden will cause hardship. The association urges that a reconsideration be given to this question."

LONDON MEDICAL EXHIBITION

THIS year's London Medical Exhibition, held at the hall of the Royal Horticultural Society, missed the splendour of last year's display when all the war-time advances were on show for the first time. There were, however, some interesting novelties. One was an electrical device whereby up to twelve students can listen simultaneously through stethoscopes to heart or breath sounds; selectivity is acute, and the apparatus should find a place both in teaching and in diagnostic work, particularly with obese subjects. Many surgical-instrument manufacturers are finding it hard to keep pace with orders. In part this is due to sales overseas, where the demand is great and still growing; but basically the cause is shortage of skilled labour. Apprentices, usually reserved during the war, are now called up; and in any case young men commonly prefer to engage in less skilled but better-paid employment, such as machine-minding, rather than undertake the long apprenticeship required before they can qualify as artisans in this field.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

THE council of the British Medical Association is prepared to receive applications for research scholarships as follows: an Ernest Hart scholarship (£200 p.a.), a Walter Dixon scholarship (£200 p.a.), and four research scholarships (each £150 p.a.). These scholarships are given to candidates qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. In addition, applications are invited for the first award of the Insole scholarship (£250 p.a.) for research into the causes and cure of venereal disease. Preference will be given to doctors. Each scholarship is tenable for one year commencing on Oct. 1, 1948. The scholar, who may be reappointed for not more than two additional terms, is not necessarily required to devote the whole of his or her time to the work of research, but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with work as a scholar. Applications must be made not later than April 30, 1948, on the prescribed form, which may be obtained from the secretary of the association, B.M.A. House, Tavistock Square, London, W.C.1.

NEW FILMS

SOME new films shown at the Ministry of Health on Oct. 30 set a high standard of technical finish, and deliver their messages well.

Patent Ductus Arteriosus is a beautifully made record of an operation for closure of the ductus carried out at Hillingdon Hospital. The effects of this anomaly on the heart and circulation are well illustrated by animated drawings, the stages of the operation are clearly shown, and the commentary is particularly good. It should prove valuable as a reminder to general practitioners that this formerly hopeless type of congenital heart disease can now be perfectly cured.

The film was made by the Crown Film Unit, and is now to be issued by the Central Office of Information at the request of the Ministry of Health, for showing to medical audiences. Copies will shortly be available in 35 mm. and 16 mm. (sound) sizes from the Central Film Library, Imperial Institute, South Kensington, London, S.W.7. The running time is 27 minutes.

The Prevention of Tuberculosis in Hospitals is an American film, running for 22 minutes, and showing a very well-organised scheme for routine miniature radiography of all patients attending a general hospital. Dr. Peter Kerley, in introducing it, noted that the incidence of tuberculosis in American hospital patients seems to be rather higher than the supposed rate here. Nevertheless, the precaution of routine radiological examination is well worth taking, and this film reveals many important details of management, besides showing how films can be developed, examined, and stored with the least possible waste of time for everybody concerned.

A one-minute film—*Diphtheria Trailer No. 10*—now being shown in cinemas at the end of news-reels brings home the immunisation lesson in a tiny animated cartoon which manages to be amusing without being frivolous, and telling without being alarming. It was made by the Central Office of Information (Halas & Batchelor Cartoon Films Ltd.) at the request of the Ministry of Health.

Your Children's Meals, the fifth film in the "Your Children" series, is for showing to general audiences, and runs 13½ minutes. It teaches a great deal about the management of meal times, the types of food that children fancy, and the ways in which sensible and sociable parents can get their children to be sensible and sociable too. The cutting of the film is clever, the sequences amusing as well as informative, and the standard of photography good. As usual the children act themselves with uncanny skill.

The film has been made by the Central Office of Information (Central Film Unit) for the Ministry of Health, and copies will soon be available in 35 mm. and 16 mm. (sound) sizes from the Central Film Library. Arrangements can be made for the film to be shown through the Central Office of Information mobile film units, on application to the Film Officer at the appropriate C.O.I. Regional Office (addresses from the C.O.I. Films Division, 83, Baker Street, London, W.1).

HOSPITAL FOR CHILDREN IN GERMANY

AT a meeting of the Save the Children Fund held in London on Nov. 6, Dr. Cyril Elgood described the work of the fund's hospital at Schlutup in Schleswig-Holstein where he is superintendent. The building, formerly the administrative block of a German war-time factory, has room for about 100 children, who come from the neighbouring camps for displaced persons. The staff includes 10 English nurses, and Dr. Elgood also trains displaced persons to help with the nursing. The stocks of penicillin for the whole area are in his charge, but they do not suffice to meet the need; for military supplies are not available for children, and German hospitals have none. The address of the fund is 20, Gordon Square, London, W.C.1.

AUSTRALIAN CHAPEL OF REMEMBRANCE AT HAREFIELD

DURING the 1914–18 war No. 1 Australian General Hospital was stationed at Harefield, and the patients received many kindnesses from the residents. Over 100 Australian soldiers and sailors are buried in the churchyard, where a service of remembrance is still held on Anzac Day. There are thus ties between Harefield and many Australian homes, and this has led to the desire to convert a chapel in the old church at Harefield into an Australian Chapel of Remembrance which will commemorate both world wars. An executive committee has been formed and is asking for £5000 for this purpose. Contributions from English friends will be welcome but the appeal is primarily addressed to Australians resident in Britain, and especially those who were with the Australian Imperial Forces in the first world war. Donations should be sent to Major N. Keith Bushell, c/o the National Bank of Scotland, 18–20, Lower Regent Street, London, S.W.1.

University of Birmingham

Dr. Harold Scarborough has been appointed a lecturer in the department of medicine.

Dr. Scarborough graduated M.B. with honours at Edinburgh in 1932 and later took his PH.D. He became M.R.C.P.E. in 1940 and F.R.C.P.E. this year, while in 1941 he was elected to the fellowship of the Royal Society of Edinb[illegible]. Dr. [illegible] held a succession of teaching and research [illegible] and for the last two years as a Bolt[illegible] at St. Mary's Hospital, London. At present he holds a Rockefeller fellowship and is working in Prof. E. M. Landl's department at Harvard. His research interests have been devoted to the problems of ascorbic acid and vitamin P, while recently he has been investigating certain aspects of peripheral blood-flow.

Royal College of Physicians of Ireland

On Nov. 7 the following were admitted to the membership: T. J. Ryan, J. W. Magner, Max Millard, G. A. C. Miller.

A painting by Mr. Henry Carr of the council of the Royal College of Surgeons of England for 1946–47, presented to Sir Alfred Webb-Johnson, the president, at a dinner held at the college on Nov. 13 in honour of Sir Alfred and Lady Webb-Johnson.

In front of the table, standing, from left to right: Sir Hugh Cairns, Mr. Philip Mitchiner.
Sitting, from left to right: Mr. L. E. C. Norbury, Mr. Zachary Cope, Mr. Geoffrey Keynes.
Behind table, standing, from left to right: Mr. Tudor Edwards, Sir Max Page, Prof. Ernest Finch, Mr. McNeill Love, Sir Reginald Watson-Jones, Prof. A. H. Burgess, the President, Mr. Henry Souttar, Prof. Harry Platt, Mr. Julian Taylor, Prof. Lambert Rogers, Prof. G. Grey Turner, Sir Gordon Gordon-Taylor.
Sitting, from left to right: Prof. Paterson Ross, Sir Heneage Ogilvie, Sir Cecil Wakeley, Sir James Walton, Prof. R. J. Willan, Mr. Scott Mason.

University of Manchester

Mr. Victor Lambert has been appointed as professor of otolaryngology.

After graduating M.B. at the University of Manchester in 1923, Mr Lambert was admitted F.R.C.S E. in 1927. He took his M.CH. in 1932 and his M.D. in 1940. Since 1935 he has been lecturer in diseases of the ear at Manchester University, and he is also consulting otologist to the department of education of the deaf, aurist and laryngologist to the Manchester Dental Hospital, and assistant lecturer in physiology. Mr. Lambert also holds appointments as aural surgeon to the Manchester Royal Infirmary, the Christie Hospital, and the Royal Manchester College of Music. He has published original work on diseases of the larynx, and has taken a particular interest in comparative anatomy.

Dr. Michael Polanyi, F.R S , professor of physical chemistry in the university, has been appointed to the chair of social studies.

Professor Polanyi graduated in medicine in the University of Budapest. Later he specialised in chemistry and he held the chair of chemistry in the Technical High School of Berlin, and taught in the Kaiser Wilhelm Institute, publishing original work on crystal structure and chemical reaction kinetics. In 1933 he accepted an invitation to become professor of physical chemistry at Manchester. His wide experience and range of interests have brought him closely into contact with investigators and teachers in social studies and in economics, and he is the author of *The Contempt of Freedom* and *Full Employment and Free Trade*. He was elected a fellow of the Royal Society in 1944, and in 1946 delivered the Riddell lectures in the University of Durham on Science, Faith, and Society. His Lloyd Roberts lecture on the Foundations of Academic Freedom was published in our columns this year.

Queen's University, Belfast

Dr A. C. Stevenson has been appointed to the chair of social and preventive medicine.

Dr. Stevenson, who is 38, was educated at Glasgow Academy and Glasgow University, where he took the degrees of B.SC. in 1930 and M.B. in 1933. After holding house appointments at the Glasgow Royal Infirmary he became resident medical officer at Highgate Hospital, London. In 1935 he took his M.R.C.P. and two years later his D.P.H. while serving as assistant M.O H. for Wakefield. In the same year he was appointed deputy M.O.H. for the borough. From 1939 to 1945 he served with the R.A.M.C. as assistant director of hygiene, West African command, and as deputy director of hygiene, Western Command. At the beginning of 1946 he was appointed to his present post of reader in the University of London at the London School of Hygiene.

Mr H. W. Rodgers has been appointed to the chair of surgery.

Mr Rodgers, who is 39 years of age, was educated at King's College School and St. Bartholomew's Hospital, where he took the Conjoint qualification in 1931, and the F.R.C.S. two years later. After holding house-appointments at Barts and clinical assistantships at St. Mark's and St. Peter's Hospital he became chief assistant to a surgical unit at Barts, and afterwards was appointed to the staff as assistant surgeon. He is also surgeon to the Radium Institute and Mount Vernon Hospital, and he holds the honorary rank of lieut.-colonel in the R.A.M.C. He has published articles on gastroscopy and diseases of the stomach, some of them being written in collaboration with Mr. N. C. Tanner and Dr. F. Avery Jones. Mr. Rodgers delivered a Hunterian lecture at the Royal College of Surgeons in 1938 on Gastroscopy, and in 1947 on the Late Results of Gunshot Wounds of the Abdomen He has also published reports for the Army on gas-gangrene and abdominal wounds. He was appointed O.B E in 1943.

Royal College of Surgeons of England

At a meeting of the council of the college held on Nov. 13, with Sir Alfred Webb-Johnson, the president, in the chair, Mr. James Wyatt was admitted as a coöpted member. Mr. V. E. Negus, Sir Stewart Duke-Elder, Mr. F. C. Ormerod, Mr. F. W. Law, and Mr. George Black were admitted as members of the court of examiners. Mr. H S. Souttar was appointed Hunterian orator and Mr. L. E C. Norbury Bradshaw lecturer.

The following were elected fellows in dental surgery:

Sir Frank Colyer, Prof. E. C. Sprawson, Colonel E. B. Dowsett, Mr. Frank Coleman, Mr. T. W. Widdowson, Mr. F. N. Doubleday, Mr. J. H. Badcock, Mr. W. Warwick James. Mr. J. G. Turner, Mrs. Lilian Lindsay, Mr. A. E. Rowlett, Mr. Bryan J. Wood, Mr. C. S Morris, Mr. Harold Round, Brigadier R. A. Broderick, Mr. J. Sim Wallace.

It was decided to institute courses of postgraduate lectures on dental subjects Dr. F S. Gorrill was appointed anatomical curator and lecturer in anatomy. Dr. B. Schofield was appointed lecturer in physiology. Leverhulme scholarships were awarded to Mr. E. S. R. Hughes and Mr. H. Daintree Johnson.

Diplomas of membership were granted to the candidates named in THE LANCET of Nov. 8 (p. 707) as having qualified to practise, and to D. J. Parr and J. C. E. Pougher. Diplomas in child health, medical radiodiagnosis, medical radiotherapy, and physical medicine were granted, jointly with the Royal College of Physicians, to the candidates named in THE LANCET of Nov. 8 (p. 707). The D M R. was also granted to D. K. Sambrook.

Society and the Individual

On Thursday, Dec. 4, the British Social Hygiene Council will hold a conference on this subject in the Livingstone Hall, Tothill Street, Westminster, S.W.1. The chair will be taken by Prof. Winifred Cullis, D SC , and Dr. E. B. Strauss, and the speakers will include Mr. Kenneth Walker, F.R.C.S., and Dr. E. H. Larkin. Tickets may be had from the council, Tavistock House North, W.C.1.

Central Midwives Board

Mr. R. J. Fenney, previously assistant secretary, has been appointed secretary and chief executive officer of the board, in succession to Mr. A. J. Bennett, who has been appointed secretary to the North-west Metropolitan regional hospital board.

University of Leeds Postgraduate Committee

Clinical meetings, open to general practitioners, will be held at 3.15 P.M. on Tuesdays, beginning on Jan. 6, in the instructional block, Leeds General Infirmary. No fee will be charged, and further information may be had from the senior administrative officer, School of Medicine, Leeds, 2.

Institute of Dermatology, London

Two alterations have been made in the lecture programme for December and January, which appeared in our advertisement columns last week. On Dec. 4 Dr. R. T. Brain will give a lecture on Filtrable Viruses, and on Jan. 14 Dr. C. W. McKenny will speak on X-ray Technique.

Spens Committees

Sir Horace Hamilton, G.C.B., has been appointed a member of these committees, which are considering the range of professional income of consultants and specialists, and of dental practitioners, in a publicly organised health service. Sir Horace, who was Permanent Under-secretary of State for Scotland from 1937 until 1946, succeeds Sir Thomas Gardiner.

Royal Society

A Royal medal has been awarded to Dr. F. M. Burnet, F.R.S., for his work on bacteriophages, viruses, and immunity, and for his contributions to the study of infectious diseases as an ecological phenomenon. The Buchanan medal has been awarded to Sir Edward Mellanby, F.R.S., for his researches *on the physiology of nutrition, especially in relation to the* causation of deficiency diseases.

Scottish Triple Qualification

The following have been admitted licentiates of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow:

Afolabi Alakija, J. M. Brownlie, Leo Charles, W. J. C. Colin-Thome, R. S. Cowie, A. M. Darwish, T. P. Edwards, P. H. T. Fok, Sidney Gordon, J. A. Gray, W. S. Hall, Maurice Harris, Patricia E. Hartley, J. M. Hillock, Emanuel Katz, D. P. Keith, Stanley Lipson, Michael Lloyd-Jones, Peter Macpherson, Hilary E. C. Millar, H. G. C. Payne, A. I. Richardson, J. R. Scott, Joan C. R. Shiell, Harry Simmons, H. S. Sloane, J. D. Stewart.

The latest monograph of the Queckett Microscopical Club, *Illuminants and Illumination for Microscopical Work*, comprises a lecture delivered by Mr. F. E. J. Ockenden. The monograph, price 2*s.* 6*d.*, is published for the club by Messrs. Williams and Norgate Ltd., 36, Great Russell Street, London, W.C.1.

Yearbook of Physical Anthropology.—A new number of this yearbook will shortly be available, and requests for copies, for which there is no charge, will be met as far as possible. Those who would like to be considered for a copy of this new edition or who still wish a copy of the first number, which covered 1945 (*Lancet*, 1947, i, 684), should apply to Dr. J. M. Tanner, Department of Human Anatomy, University Museum, Oxford.

Appointments

Bottomley, Janet, M.D. Lond., F.R.C.S., M.R.C.O.G.: first assistant and registrar, gynæcological and obstetric department, London Hospital.

Bourdillon, J. F., B.M. Oxfd, F.R.C.S.: senior registrar, orthopædic and fracture department, Addenbrooke's Hospital, Cambridge.

Kemp, T. A., M.B. Camb.: asst. physician, St. Mary's Hospital, London.

Nash, D. F. E., F.R.C.S.: asst. surgeon, St. Bartholomew's Hospital, London.

Pilcher, M. F., M.B. Lond.: orthopædic registrar, Hospital for Sick Children, Great Ormond Street, London.

Thompson, Walter, M.B. Leeds, F.R.C.S.: chief assistant to a surgical unit, Manchester Royal Infirmary.

London County Council Hospital Service:

Catterall, R. C. F., M.CHIR. Camb., F.R.C.S.: surgeon specialist.

Metcalfe, R. H., M.A., M.D., M.CHIR. Camb., F.R.C.S.: surgeon specialist.

Thomas, R. G., M.B. Lond., F.R.C.S.E.: asst. surgeon specialist.

Diary of the Week

NOV. 23 TO 29

Monday, 24th

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
3.45 P.M. Mr. S. Mottershead: Blood-supply of the Hindgut.
5 P.M. Prof. R. J. S. McDowall: Shock.

Royal Society of Medicine, 1, Wimpole Street, W.1
5.30 P.M. *Odontology.* Miss E. M. Knowles: Survey of Denta Condition of Children in Day Nurseries and Residentia War-time Nurseries.

Medical Society of London, 11, Chandos Street, W.1
8.30 P.M. Mr. E. W. Riches, Mr. W. Somerville Mack, Mr. Ronal Reid: Tumours of the Bladder.

Institute of Laryngology and Otology, 330, Gray's Inn Road W.C.1
6 P.M. Mr. Geoffrey Gateman: Cinematograph films on Organi Disorders of the Larynx and on Bronchial Neoplasms b Dr. Paul Hollinger.

Illuminated Engineering Society
6 P.M. (2, Savoy Hill, W.C.2.) Prof. Hamilton Hartridge, F.R.S. Physiology of Vision.

Tuesday, 25th

Royal College of Surgeons
3.45 P.M. Dr. J. Whillis: Anatomy of the Œsophagus.
5 P.M. Dr. F. C. Courtice: Oxygen and Carbon-dioxide Transpor

Royal Society of Medicine
8 P.M. *Medicine.* Sir Allen Daley: Acute Anterior Poliomyeliti Dr. Margaret Macpherson: Atypical Primary Tuberculou Lesions. Dr. J. E. Capes: Use of Tubular Blockade i Penicillin Therapy.

Institute of Dermatology, 5, Lisle Street, W.C.2
5 P.M. Dr. I. Muende: Pathological demonstration.

Edinburgh Post-Graduate Board for Medicine
5 P.M. (Royal Infirmary.) Dr. J. L. Henderson: The Child Inheritance.

Wednesday, 26th

Royal College of Surgeons
3.45 P.M. Mr. R. J. Last: Segmental Innervation of Lim Musculature.
5 P.M. Prof. A. C. Frazer: Fat Metabolism.

Royal Society of Medicine
5 P.M. *Endocrinology.* Prof. H. L. Sheehan, Dr. A. W. Spence Dr. Russell Fraser, Dr. S. L. Simpson: Simmonds' Disease.

Institute of Laryngology
11 A.M. Prof. T. Pomfret Kilner: Plastic Surgery.

Royal Institute of Public Health and Hygiene, 28, Portlan Place, W.1
3.30 P.M. Dr. Mary Sheridan: Hygiene in the Nursery an Play-room.

Thursday, 27th

Royal College of Surgeons
3.45 P.M. Prof. John Kirk: Fœtal Circulation.
5 P.M. Dr. D. J. Bell: Carbohydrate Metabolism.

Society of Medical Officers of Health
5.30 P.M. (B.M.A. House, Tavistock Square, W.C.1.) Sir Alle Daley: My American Diary.

Medico-Legal Society
8.15 P.M. (26, Portland Place, W.1.) Dr. W. R. H. Heddy: Deat on the Roads.

Honyman Gillespie Lecture
4.30 P.M. (Edinburgh Royal Infirmary.) Prof. J. Chassar Moir November 1847 and its Sequel.

Friday, 28th

Royal College of Surgeons
3.45 P.M. Dr. P. R. Peacock: Experimental Study of Brea Cancer.
5 P.M. Dr. L. E. Glynn: Hepatic Dysfunction.

Royal Society of Medicine
5 P.M. *Pædiatrics.* Dr. Ian Skottowe, Dr. A. A. E. Newth Dr. *Mildred Creak*: Child Guidance in the New Healt Service.

London Chest Hospital, Victoria Park, E.2
5 P.M. Dr. Shirley Smith: Acute Heart-failure.

Middlesex County Medical Society
2.45 P.M. (Royal National Orthopædic Hospital, Stanmore. Mr. John *Cholmeley*: *Management of* Anterior Polio myelitis—Early and Late. Dr. J. O. F. Davies: Epidemio logy of Anterior Poliomyelitis.

Royal College of Physicians of Edinburgh
5 P.M. Dr. R. M. Stewart: Clinical Features and Pathologica Anatomy of Infantile Hemiplegia. (Morison lecture.)

Saturday, 29th

Medical Society for the Study of Venereal Diseases, 11 Chandos Street, W.1
2.30 P.M. Dr. Eric Wittkower: Psychological Aspects of Venerea Disease.

Corrigendum: *Thorium-X.*—The correct reference t Mr. Henry Corsi's papers (mentioned by Dr. Carleton an Dr. Whittle in their letter last week) is *Lancet*, 1943, ii, 346.

A HEPATIC SYNDROME OF WIDE DISTRIBUTION

ILLUSTRATED BY LESIONS IN MALARIA AND BLACKWATER FEVER

BRIAN MAEGRAITH

From the Department of Tropical Medicine, Liverpool School of Tropical Medicine

CLINICAL manifestations of liver disease may appear in all forms of human malaria at any stage. They are most common in *P. falciparum* infections, and extreme examples present the syndrome of bilious remittent fever in which the liver is enlarged and tender, jaundice appears early, associated with either the indirect or biphasic van den Bergh reaction, and there is bilious vomiting with severe and often intractable diarrhœa. Bilirubin is usually, but not always, present in the urine (Manson-Bahr 1945, Fairley 1932–33). A clinical picture very similar to bilious remittent fever sometimes develops in blackwater fever.

Henry (1932) maintains that the liver is always affected in malaria, but this view is not widely accepted. Nevertheless in uncomplicated malaria there may be enlargement of the liver with some jaundice and other signs of liver disturbance, including deviations in serial hepatic-function tests and the passage in the urine of bilirubin, urobilin, and urobilinogen (Rudolf 1927, Allen and Norris 1944, Hughes and Bomford 1944, Kean and Smith 1944, Kopp and Solomon 1943, Mirsky et al. 1944, O'Leary et al. 1929, Lippincott et al. 1945, 1946, Fredricks and Hoffbauer 1945, Carter and McLagan 1946, Glenn et al. 1946).

LIVER CHANGES IN MALARIA AND BLACKWATER FEVER

In active malaria associated with deviations in hepatic-function tests liver-biopsies have occasionally been performed and have revealed no evidence of structural alterations (Fredricks and Hoffbauer 1945). In fatal cases, however, important pathological changes are often observed.

At necropsy after acute malaria the liver is usually enlarged and varies from dark red to black according to the amount of pigment present. The cut surface bleeds easily and is often fatty. Occasionally there are small hæmorrhages in the central regions of the lobules.

The histological picture is one of central zonal degeneration and necrosis. The lobules are indistinctly demarcated. The congested organ shows the central vein and its tributary sinuses filled with erythrocytes, many of which contain parasites. When anæmia is severe, the central vein and sinuses appear dilated and empty. There is little evidence of stasis or thrombosis in the blood-vessels, whose endothelium is not much affected. Some writers have recorded "mechanical obstruction" of the sinuses and occasionally of the larger blood-vessels by collections of pigmented macrophages, free parasites, and pigment; stasis; thrombosis; and agglutination of erythrocytes, some containing parasites. Such obstruction appears to be rare. Klotz (1929), for instance, found no evidence of it in patients who died of malignant tertian malaria in West Africa, and he stated that, so far as vascular occlusion was concerned, the picture in the liver in *P. falciparum* infections was "nothing like" that in the brain.

The Kuppfer cells and the littoral cells of the sinuses are often grossly swollen and filled with erythrocytes, parasites, and debris. These swollen cells appear in places to obstruct the lumen of the sinuses. The columns of polygonal cells are often widely separated and appear to be distorted and pushed apart by the hypertrophied Kuppfer cells.

The polygonal cells contain hæmosiderin but not malarial pigment. They may show only mild acidophilic granular degenerative changes, but fatty degeneration is common and is most evident in the cells of the central zone of the lobule or, when these cells are necrotic, in the cells at the periphery. More severe degeneration and necrosis have often been reported in human and animal malaria and in blackwater fever.

Klotz (1929) has provided one of the clearest descriptions of the liver lesions. In patients who died of *P. falciparum* infections the appearance of the cut surface of the liver was one of "reversed nutmeg details," the lobules showing a yellowish-grey centre and a peripheral red zone. Necrosis of the liver cells was found in the inner two-thirds of the lobule and was most prominent in those cells surrounding the central vein. In this region the cytoplasm was granular, vacuolated, fatty, and acidophilic, and the nuclei stained feebly or were pyknotic, broken up, or absent. The necrosis was sharply limited, and the cells at the periphery of the lobule were relatively unaffected. The central veins and sinusoids were deeply congested. Klotz believed this dilatation was very significant and developed before the changes in the hepatic cells.

Similar changes have been observed by other workers in human and simian malaria (Rigdon and Stratman Thomas 1942, Kean and Smith 1944, Taliaferro and Cannon 1936, Taliaferro and Mulligan 1937, Gaskell and Millar 1920, Dudgeon and Clarke 1919).

Some degree of atrophy of the polygonal cells is also commonly seen in malaria. Gaskell and Millar (1920), for instance, described "rows of shrunken cells" in the central zone of the lobule. The atrophic cells show reduction of cytoplasm, which is often fragmented, and some minor changes in the nuclei.

In severe malaria and blackwater fever the bile in the gall-bladder is tarry and inspissated, and the liver cells may show evidence of biliary obstruction, with the canaliculi distended with greenish bile. These cellular changes are again most prominent in the central zone of the lobule. Occasionally, even in the presence of severe central necrosis, there may be no apparent biliary changes (Whipple 1909, Dudgeon 1920, Paterni 1923, Klotz 1929).

Cellular infiltration of Glisson's capsule has been described, especially in cases with a history of long-sustained or frequently recurring attacks of malaria. The cells are lymphocytic in type and do not usually invade the cells of the lobules. They are confined as a rule to the region of the portal vessels.

PATHOGENESIS OF CENTRAL-ZONE HEPATIC NECROSIS

Vascular Changes

The hepatic lesions in malaria in many ways resemble those developing in right-sided heart-failure, associated with tissue anoxia arising from interference with the escape of venous blood from the liver. In a few cases of malaria the effects of a failing heart probably contribute towards the pathological changes in the liver (Gaskell and Millar 1920), but in most cases almost identical liver lesions appear without any evidence of cardiac failure. This is especially true of blackwater fever, in which liver lesions are very common and cardiac failure is rare except as a strictly terminal event. Some patients in whom liver lesions are well developed die in a state resembling shock (Atchley 1930), a condition in which right-heart failure does not occur and indeed the venous return to the heart is much reduced; hence "back-pressure" effects originating in the vena cava cannot play any part in the production of the liver changes (Wiggers 1918, Mann 1919, Moon 1938, Rigdon 1942, Maegraith 1944). The similarity of the lesions of shock to those of "passive" congestion in the liver as well as other organs has been emphasised by Moon (1938).

Some explanation other than right-sided heart-failure must therefore be sought to explain the hepatic lesions in most cases of malaria and blackwater fever. The congestion and dilatation of the lobular vessels may result from obstruction to the blood-flow arising from changes in the vessels themselves. The blood-flow through the vessels may be to some extent inhibited by: (1) intravascular agglutination of red cells, which occurs, however, only late in the disease; (2) stasis or thrombosis, of which there is very little firm evidence (stasis might be expected to follow changes in the endothelium leading to increased permeability, but in the liver the endothelial cells are physiologically so permeable that no further appreciable local loss of fluid takes place even when the cells are damaged); and (3) mechanical effects arising from hypertrophy, hyperplasia, and degeneration of the Kupffer and littoral cells.

The balance of histological evidence indicates that these processes can affect the flow through the lobule only slightly. There must therefore be some other form of resistance to the venous flow, and this is most probably an active obstruction due to constriction of some elements of the hepatic venous vessels. Such constriction would reduce the hepatic venous outflow, and it is probably this reduction of venous flow and the associated anoxia arising from it which give rise to the hepatic lesions observed. The syndrome of Chiari (1899) illustrates well the effects of obstruction to the hepatic veins. Here the orifices of the larger veins are obstructed by thickening of the intima and sometimes suddenly by thrombosis. When the obstruction is acute, the cells of the central zone of the lobules are completely destroyed and there is intense congestion of the central vein and its tributary sinuses. In cases of more gradual development there is "extensive atrophy" of the hepatic cells in the centre of the lobule with distension of the central vein and sinuses. Thompson and Turnbull (1911) observed that in this syndrome there is a "remarkable association of a liver showing extreme atrophy with venous congestion with a heart in which there is no evidence of chronic embarrassment."

This picture is the same as that seen in malaria, in which there is neither constant cardiac failure nor any evidence of thrombosis or other anatomical occlusion of the hepatic veins. Since interference with the drainage of venous blood from the hepatic lobules arises somewhere between the lobule and the vena cava, there must be obstruction (presumably vascular constriction) in the hepatic venous tree.

Cellular Changes

The vascular changes discussed above lead to slowing of the intralobular circulation and to progressive stagnant anoxia (Peters and Van Slyke 1931) interfering with the oxygen supply to the tissue cells. Cellular damage arising from this anoxia is at first reversible, but finally becomes irreversible and goes on to degeneration and necrosis. This anoxia is probably the principal cause of the changes found in the liver cells, but there are contributory factors in malaria which aggravate the anoxia arising from the intralobular circulatory incompetence. The invasion of erythrocytes by the plasmodia leads to a lowering of the oxygen-carrying capacity of the infected cells, and the anoxæmia so produced is augmented by the anæmia arising from the destruction of both infested and non-infested cells. These general processes may be further enhanced in malaria, but not in blackwater fever, by the local tissue effects of diffusible products of the parasitic metabolism, such as pyruvic acid, lactic acid, and possibly other substances released at sporogony of the parasites. The malarial pigment is not involved (Anderson and Morrison 1942). In the production of the final picture of degeneration a necrosis other factors are also involved, including t nutritional status of the patient and the hypoprote æmia prevailing in many cases.

It is possible also that the anoxic state of the hepa tissue, or some change in it arising indirectly fr the malarial infection, produces changes in the c stituents of the cells and renders them auto-antige and capable of producing anti-liver-cell antibodies wh react with the antigens and cause tissue damage. G (1946) has suggested that some process of this sort m be involved in the lysis of erythrocytes in malaria a has shown that the yellow-fever virus will prod auto-antigens in rhesus-monkey livers.

There is no need here to discuss these contribut factors in detail, since there is ample evidence to sh that the essential factor in the cellular changes is ano resulting from alterations in intralobular blood circulati It is not very easy to see, however, why the les should be centrally placed, since pure stagnant ano should affect all areas of the lobule equally. Poss *the depleted oxygen-carrying powers of the blood* concerned here, and the tissue at the periphery of lobule, which receives the arterial blood first, has better opportunity of securing its oxygen supply th that in the centre of the lobule. Specific sensitiv of the central cells to chemical poisons and some kind collateral circulation between sinuses in the periph of the lobule have also been suggested, without mu supporting evidence.

MALARIA AS AN EXAMPLE OF A GENERAL PROCESS

We have seen that the hepatic lesions of malaria a blackwater fever are similar. In severe cases t picture is one of dilatation and possibly congestion, the central lobular veins and tributary sinuses. The is degeneration and necrosis of the polygonal cells of t central zone of the lobule, resulting, so far as can judged, from anoxia arising mainly from obstruction the venous outflow from the liver.

The conditions referred to above are clearly anox but the central zonal necrosis often appears in circu stances which are not so obviously anoxic. For instan it is not easy to see at first sight how anoxia cou develop in chloroform or carbon-tetrachloride poisoni except in the form of histotoxic anoxia arising fro the direct action of the chemical agent on the tiss oxidation systems (Keilin 1925). The same difficul arises in explaining the liver lesions in burns and ma of the experimental procedures such as ligation of th portal vein or hepatic artery and the production Eck's fistula. We believe that the only explanatio can be that in all these conditions there is an alteratio in the intrahepatic blood-flow which leads to stagnat anoxia. This still does not explain the central distr bution of the degeneration, and it seems necessary t postulate also either some process whereby most of th oxygen of the blood is removed by the cells in th periphery of the lobules, such as we have mentione elsewhere, or the shunting of blood away from th centre of the lobule so that the peripheral cells receiv a better supply than those in the centre.

No particular specific agent has been implicated i the pathogenesis of the liver lesions in either malari or blackwater fever. These lesions may therefore b regarded as examples of a general pathological reaction the non-specific nature of which is emphasised by th wide variety of clinical conditions in which it occurs Thus central lobular necrosis has been recorded i right-sided heart-failure; poisoning by various chemica agents, such as chloroform (Whipple and Sperry 1909) heat hyperpyrexia (Malamud et al. 1946); severe burn (Hartman and Romence 1943), especially after tanning (Wilson et al. 1938, Erb et al. 1943); acute postoperativ of the liver (Sutton 1943); various allergic ; pernicious anæmia; secondary anæmias, severe hæmorrhage; and babesia infections in Experimentally, similar lesions have been pro- by the administration of various poisons, such tetrachloride and phosphorus (Williamson and 1923), by long exposure of animals to low atmo- oxygen tensions (Rosin 1928, Rich 1930), and asions but not always (Cameron and Mayes 1930) interference with the blood-supply to the liver (Rous Larimore 1920, Bainbridge and Leathes 1906–07, et al. 1922, Whipple and Hooper 1916).

The appearance of identical pathological changes in such diverse conditions indicates a common factor. It is our contention that the lesions develop primarily because of alterations in intrahepatic blood-flow, and that the cellular changes are brought about by localised anoxic conditions.

Rous and Larimore (1920) obtained central necrosis by ligating branches of the portal vein, and they concluded it arose from venous "back pressure." They noted, however, that "atrophy is least at the periphery of the lobule where oxygenation is most." MacCallum), Resnik and Keefer (1925–26), and Rich and Resnik (1926) studied the development of central zonal degeneration under various conditions and concluded that the basis of the lesion was deficient oxygenation of the blood, which progressively increased from the periphery to the centre of the lobule. Rich (1930) examined livers from many cases of anæmia and found central degeneration in all of them; dietetic factors had been excluded. He concluded that "atrophy and central necrosis will occur as the result of anoxæmia in the absence of heart-failure, and in the absence of any evidence of passive congestion of the heart, spleen, or other organs." Anoxia, therefore, whether due to anæmia, stagnant circulatory conditions (right-heart failure), or lowered oxygen tension in the respired air, will produce central zonal cellular changes in the lobules.

In the absence of right-heart failure, as we have seen in malaria, the stagnant anoxia in the liver probably arises from active obstruction to the venous outflow, which leads—for example, in Chiari's disease—to a centrally placed lobular lesion. We suggest that the obstruction to the venous outflow arises from constriction of some or all of the hepatic venous tree, and that this is the basic mechanism in the production of the lesions in the conditions referred to. (There is evidence that this may also be the case in heart-failure.)

Acute constriction of the hepatic veins in dogs is readily produced by anaphylactic shock (Simonds and Brandes 1927), the trigger dose giving rise to a rapid swelling of the liver, a fall in blood-pressure, and a diminution of venous return to the heart. The hepatic venous flow is greatly reduced. On section the vessels are found to be intensely congested, the maximal effect being on the central and tributary sinuses. Similar obstruction to the hepatic venous flow may be produced by histamine (Mautner and Pick 1929) and peptone (Simonds and Brandes 1929).

Bauer et al. (1932) obtained clear evidence, in perfusion experiments, of the existence of a "sphincter-like" mechanism which could regulate to some extent the venous outflow from the dog's liver. This "sphincter" could be activated by histamine and relaxed by stimulation of the sympathetic nerves to the liver or by small doses of adrenaline. It was located near the caval ostia of the hepatic veins. Physiological evidence of a similar "sphincter" has not been obtained in man, but there is some anatomical evidence suggesting that the musculature of the larger hepatic veins may be specialised to act as sphincter. If such a hepatic venous sphincter does exist in man it presumably reacts to shock and histamine by constriction, which would explain the hepatic lesions of, for example, algid malaria and blackwater fever. There may be constriction of any part of the venous tree, including small vessels like the sublobular veins, or large vessels like the hepatic veins, or even the hepatic vena cava.

Deysach (1941) has brought forward evidence for the existence of "sluice vessels" which drain directly from the sinusoids into the sublobular veins; these were present in all mammals, independent of the degree of musculature of the hepatic veins, and their constriction impeded venous drainage.

The mechanism of the reflex is still highly speculative. Since the classical experiments of Francois-Franck and Hallon (1896) and Burton Opitz (1911–14) many observers have studied the effects of nerve stimulation and of adrenaline on the liver, both in situ (Griffith and Emery 1930, Edmunds 1915) and perfused (McMichael 1932, Bauer et al. 1932). The consensus of opinion is that both adrenaline and stimulation of the sympathetic nerves cause a diminished inflow of blood coupled with an increased outflow (see Franklin 1937). Bauer et al. (1932) go further and find that, whereas large doses of adrenaline reduce the outflow, smaller doses hasten it. Large doses of adrenaline lead to hepatic engorgement (Bainbridge and Trevan 1915) and even to central necrosis (Drummond 1904). Histamine (Baer and Rössler 1927, Mautner and Pick 1929), peptone, anaphylactic shock, and digitalis (Katz et al. 1938) all diminish the outflow from the liver of dogs. The effect of acetylcholine and of vagal stimulation is equivocal, no great change usually being noted; diminished outflow has, however, occasionally been recorded. Adrenaline reverses the effect of histamine and of peptone.

As we pointed out above, in the dog the ostia of the hepatic veins are surrounded by a thick coat of smooth muscle which appears in induced shock to be the primary factor in restricting the venous outflow (Arey and Simonds 1920). No such localised thickening of the venous wall is found in man, though Elias and Feller (1931) report that the smooth muscle present is capable of raising folds in the intimal wall. The smaller venous tributaries are, however, well supplied with muscle, and various observers believe that resistance to venous outflow may also take place in these vessels (Bauer et al. 1932, Mautner and Pick 1929, Baer and Rössler 1927).

The initiation of the vascular changes in the liver is probably reflex in origin. In general states, such as shock, the reflex may be initiated by extrahepatic stimulation and represent part of a generalised, possibly protective, mechanism designed to restrict the blood-flow through the viscera. It is interesting to note here the frequent association of renal and hepatic changes. Possibly the so-called hepatorenal syndrome has its origin in such reflex activity, whereby the central lobular lesions and those of renal anoxia (Maegraith et al. 1945) are simultaneously produced. In conditions in which the liver is primarily affected the process may be initiated solely by intrahepatic stimuli, possibly arising from the damage to the cells, or directly from toxic substances—e.g., chloroform—acting on them though there is evidence that so-called "liver poisons" are part of a generalised pathological process (Williamson and Mann 1923).

SUMMARY

The hepatic lesions in severe malaria and blackwater fever are distributed mainly in the central zone of the lobules.

The lesions are non-specific and are essentially similar to those of a great variety of other conditions.

The cellular changes develop primarily from anoxia.

We maintain that the lesions arise from stagnant anoxia resulting from active obstruction to the venous outflow from the liver, and that this arises from constriction of some part of the hepatic venous tree.

This constriction is brought about mainly by nervous reflexes which may have their origin within or outside the liver. In the latter case they probably explain the frequently reported relation between hepatic and renal disturbances.

Postscript.—Later evidence suggests that the vascular reflex described above is not the only intrahepatic mechanism causing centrilobular anoxia. Professor Himsworth has shown that swelling of the parenchymal cells may partially obstruct the flow of blood through the liver, giving rise to centrilobular degeneration. Working independently we have come to the conclusion that this happens with CCl_4 poisoning, though in some cases the reflex postulated above may contribute. We still believe that a vascular reflex is of great importance in producing centrilobular degeneration.

EPIDEMIC MYALGIA OR BORNHOLM DISEASE IN SOUTH INDIA

A REVIEW OF 19 CASES

H. J. Hamburger
M.D. Hamburg
MAJOR R.A.M.C.,
SURGICAL SPECIALIST

C. McNeil
M.B. Camb.
MAJOR R.A.M.C.,
GRADED PHYSICIAN

From the British Military Hospital, Bangalore, India Command

OUTBREAKS of epidemic myalgia or Bornholm dise arouse interest mainly because of the difficulties of t differential diagnosis. So far as we know, no outbrea have been reported from tropical or subtropical countr except Alabama (Nichamin 1945) and a Caribbe island (McDaniel 1944).

Benign epidemic pleurisy (Williamson 1924) clos resembles it and has been observed by Scadding (19 in the Middle East, and Roche and Smiddy (19 in India. The latter paper, however, seems to deal m with an upper respiratory infection.

In twelve weeks, from the end of June to the e of September, there were 19 cases of a benign myal syndrome in a South India garrison, 14 of these ca occurring in one unit; 2 of the patients were Indian a 17 were Europeans. The clinical picture was in ea case ill defined, but that of the series as a whole tall very well with Sylvest's (1932) description of Bo disease. In all our cases the myalgia predominat distinguishing them from the series observed by Scaddi (1946) and Roche and Smiddy (1946). In fact, 5 o of 20 attacks observed were suspected of being ac abdominal emergencies, the myalgia giving the impress of rigidity; and 2 of the patients underwent explorato laparotomy.

We wish to draw attention to the possibility of t occurrence of Bornholm disease in India, and the ne to distinguish this malady from other acute upp abdominal or thoracic pains. Our findings are summaris in the accompanying table.

CLINICAL PICTURE

Onset was sudden, with severe pain in the lower p of the chest and/or upper abdomen.

Pain was aggravated by any movement of the affect muscles, such as deep breathing, coughing, pressin or rotating the trunk. The patients repeatedly volu teered the information that laughing particular exacerbated the pain; in one case the attack start during a fit of laughter. The centre of the pain was eith in the upper epigastrium, radiating to the side, or in o hypochondrium. It lasted, on the average, 48 hour if longer, it was interrupted by remissions of vario lengths.

Temperature ranged between 100° and 102°F in abo half the cases; in the other half it was normal. In th pyrexial cases, the temperature *usually* returned t normal with the disappearance of the pain. Th pulse-rate was not raised in proportion to th temperature.

In practically all cases the affected muscles were tende There were no other physical signs; no pleural frictio was heard. There were no characteristic changes in th blood picture, except a suggestion of a mild relativ lymphocytosis. In 15 cases examined radiologically no abnormalities of the chest were detected.

ILLUSTRATIVE CASE-RECORDS

Case 5.—Acute onset of continuous stabbing pain i right lower chest and upper abdomen six hours before admission. Pain was aggravated by deep breathing.

On examination: temperature 98°F, pulse-rate 88, respirations 18. Chest movements diminished; percussion not nt: breath sounds normal, but poor air entry at both bases. Board-like rigidity of abdominal muscles. Maximal point of tenderness appeared to be a little below the xiphisternum. Patient looked toxic, with congested face. Radiography of the chest negative.

Exploratory laparotomy for a suspected perforated peptic ulcer showed no abnormality. Temperature settled within [illegible] hours, but it was difficult to assess the duration of the pain owing to the abdominal incision. White-cell count 7000 per c.mm. (polymorphs 86%). Convalescence uneventful.

Case 14.—Admitted with 24 hours' history of pain, of sudden onset, in left side of chest. This started while he was on a march, and was so severe that he had to fall out. He then went to bed, with a temperature of 100°F. In the morning he had a violent frontal headache and felt he could not take a deep breath.

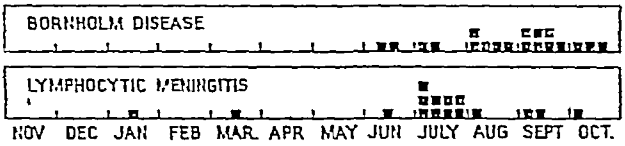
On examination: temperature 98°F, pulse-rate 70, respirations 20. Definite tenderness of muscles in 3rd–5th left intercostal spaces in anterior axillary line. Pectoral muscles tender on firm pressure. White-cell count 6800 per c.mm. (polymorphs 53%, lymphocytes 38%). Chest radiogram negative. Urinary chlorides normal.

Pain became gradually less severe, and patient was completely free of it five days after admission. He had been afebrile since admission.

COMMENTS

The outstanding clinical features of epidemic myalgia vary from outbreak to outbreak. As in Sylvest's (1932) description, upper epigastric and low chest pain, muscular tenderness, mild pyrexia of short duration, and embarrassment of breathing were prominent.

The importance of the differential diagnosis is shown by the fact that 5 cases simulated abdominal emergencies so closely that 2 of them were operated on by different surgeons. It was the opinion of all the medical officers who examined these cases that they were indistinguishable from an early acute abdomen, and it is only in the context of the whole series of the cases that similar errors were avoided. It is perhaps helpful to note that the collapse of classical intestinal perforation was not present. Rather did our patients have a toxic look, with a congested face and drowsy appearance.



Coincidence of outbreaks of Bornholm disease and of lymphocytic meningitis in South India.

The tendency of the pain to shift from the centre to the side, and its relation to respiration, suggests pleurisy, appendicitis, cholecystitis, and amœbic or other hepatitis. We are, however, satisfied from clinical observation

Case No.	Pain		Pyrexia	Leucocyte-count			Tenderness of muscles	Remarks
	Site	Duration		Day	Total (per c.mm.)	Lymphocytes (%)		
1	Lower abdomen	5 hr.	Nil	..	..	..	+	Rigid abdomen; laparotomy performed; nil abnormal found

20	Right and left hypochondrium, and epigastrium	72 hr.	Nil	2nd	6800	..	−	..

and the invariably benign course that none of these conditions was present in any of our patients.

White-cell counts varied widely, as reported by other observers. No reduction in the hæmoglobin level was noted in the cases examined. The age and sex incidence, all cases being men below the age of 30, is not significant, as we were dealing with a military population of young men.

The description by Goldstone and Le Marquand (1946) of 13 cases in British soldiers in West Africa of a syndrome simulating acute abdominal disease seems to us to be a perfect description of an outbreak of Bornholm disease, except for one atypical case in which the pain was in the upper abdomen and back. Their contention that these cases (which like ours recovered spontaneously and rapidly) were abortive forms of perinephric staphylococcal infection does not appear to be supported by any objective findings. The benign clinical course of their cases (with the one exception) is to all intents and purposes identical with that in our series.

Huss (1934), Lindberg (1936), and Howard et al. (1943) have recorded an associated lymphocytic meningitis or meningo-encephalitis. None of our cases showed any neurological signs, but there have recently been several cases of benign lymphocytic meningitis in this area. The monthly incidence of lymphocytic meningitis and Bornholm disease is shown in the accompanying figure.

The climate in this station is subtropical. Naturally, the question arose if these muscular spasms could not be the result of sodium-chloride depletion. We therefore estimated the urinary chlorides in some cases but found no deficit, even in two patients in whom the attack had started immediately after long route marches.

In an epidemic in Mobile, Alabama, the prevailing climate being that of excessive rainfall with periods of continuously high humidity, warm moist weather was thought to be a precipitating factor (Nichamin 1945). The present cases all occurred during an unusually late and heavy monsoon with long periods of moist heat. One must, however, not forget that most epidemics have been observed in countries such as Denmark, Norway, and Iceland. Warm moist weather there and in South India are very different. We have convinced ourselves that the men in the most affected unit were not living under conditions of overcrowding, there being one room for every two soldiers.

In the Mobile epidemic the patients were left for an appreciable period with marked debility. This was not so in the present epidemic, as all the patients returned to full military duty immediately after discharge from hospital.

SUMMARY

A series of 19 cases of Bornholm disease or epidemic myalgia occurring in South India is reviewed.

In 2 cases the rigidity of abdominal muscles led to exploratory laparotomy.

We wish to thank Lieut.-Colonel C. Greenway, R.A.M.C., officer commanding this hospital, for his interest and permission to publish these cases, and Capt. E. A. Spriggs, R.A.M.C., graded physician, for his help in collecting the clinical data.

SYMPTOMS DUE TO MECKEL'S DIVERTICULUM

SELWYN TAYLOR
M.Ch. Oxfd, F.R.C.S.
ASSISTANT LECTURER IN SURGERY, POSTGRADUATE MEDICA
SCHOOL OF LONDON; LATELY SURGICAL REGISTRAR, KING'S
COLLEGE HOSPITAL

THE discovery of a Meckel's diverticulum during laparotomy must come as a surprise to most surgeon for it is an uncommon congenital abnormality. Harkin (1933), who collected all those recorded where complet examination of the gastro-intestinal tract was made pos mortem, found that in 25,149 necropsies it was presen on 327 occasions—an incidence of 1·3%. Often th diverticulum is merely an incidental finding when th abdomen is opened for some quite different reason rarely it is itself the site of disease, and on this accoun it is seldom if ever incriminated before operation. Amon 69,000 admissions to the Truesdale Hospital Atwoo (1946) has reported 37 cases with symptoms due t a Meckel's diverticulum. In the records of King' College Hospital there are numerous references to th finding of Meckel's diverticulum during abdominal operations, but only 11 times in eighteen years (1928–45) was it the actual cause of symptoms which necessitate surgical intervention. Thirteen cases are briefly reviewe below, with the addition of one of different causation, a a result of which it is tentatively suggested that Meckel' diverticulum may be involved in the pathogenesis o chronic as well as acute abdominal pain.

Developmentally the vitelline duct communicates a an early stage between the yolk-sac and the midgut o the embryo. Normally it is obliterated from the umbilicus inwards, and therefore the intestinal end more often remains patent. It is this tube-like structure which is called Meckel's diverticulum and it may show any stage of involution, from complete patency between umbilicus and gut to a small sac ending in a fibrous cord attached to the anterior abdominal wall, or merely a free blind sac. Wilson (1942) classified the types as follows:

(1) Connexion between umbilicus and gut persists as a fibrous band or as an intestinal fistula.
(2) Umbilical portion of duct persists.
(3) Intestinal portion of duct persists.

Type 3 is the commonest finding and was the one first described by Meckel (1809, 1812).

ACUTE SYMPTOMS

In the accompanying table are collected the 11 cases of acute surgical conditions due to a Meckel's diverticulum.

The complications arising in connexion with Meckel's diverticulum are briefly as follows:

(1) Intestinal obstruction due to a band or to volvulus.
(2) Inflammation; perforation.
(3) Intussusception.
(4) Ulceration of heterotopic gastric mucosa; hæmorrhage indicated by melæna; perforation.
(5) Foreign body.
(6) Neoplasm.
(7) Aberrant pancreatic tissue.
(8) Strangulation in hernial sac (Littré's hernia).

1. *Intestinal obstruction* is the commonest complication and is either due to direct pressure on a loop of gut or to an actual volvulus (Rothman and Zetena 1943) caused by the rotation of gut round a diverticulum attached at its tip to the abdominal wall. Cases 2, 4, 7, and 11 in the table fall into this category, and the prognosis depends on how early the intestinal obstruction is treated.

---

* During the war years, however, there was not the usual admission of patients.

Inflammation or diverticulitis (sometimes progressing [illegible]) simulates appendicitis so closely that the diagnosis is unlikely to be made. Rousseau Martin (1943) reported the case of a girl, aged 15 who complained of pain in the right lower quadrant the abdomen. There were four attacks of pain in months, each lasting six hours and being preceded nausea and followed by vomiting. The surgeon was satisfied with the diagnosis of appendicitis and, the acute symptoms had subsided, a barium mination was done, with the result that a four-hour showed a pear-shaped sac in the terminal ileum; appendix did not fill. This shows that in favourable mstances a Meckel's diverticulum may be demon- ed radiologically, which may be important in the osis of abdominal pain (see below).

Intussusception is a particularly lethal complica- of Meckel's diverticulum. It occurred twice in this s but is not common. Of Atwood's (1946) series of cases of Meckel's diverticulum only 1 developed an usception through inversion of the diverticulum. ms (1933), reviewing the cases published earlier, d only 160, and added 2 more. He pointed out that usception due to an invaginated Meckel's diverti- m differed from the ordinary intussusception in four s: it occurred in older children; there was usually story of a previous attack; the progress was more ic and more mild; and vomiting was usually more se.

4. *Ulceration of heterotopic gastric mucosa* (hæmor- e indicated by melæna) is an interesting finding in diverticulum. There was 1 case of this in the present s, and the leiomyoma in case 10 may well have arisen ectopic gastric tissue, but this could not be demon- ted after the widespread secondary changes had n place. Marshall (1942), reviewing 12 consecutive of diseased diverticula, propounded the view that was the commonest complication in the younger nt, whereas the older age-group tended to develop tinal obstruction or inflammatory lesions. Aschner Karelitz (1930) discussed the condition, mentioning previously recorded cases of Meckel's diverticulum taining gastric mucosa, in 12 of which ulceration had n place. They added 2 cases of their own in which bleeding from the bowel was the presenting sign. Mr. Rupert Corbett has kindly sent me particulars of 2 further cases of bleeding from Meckel's diverticulum. Since a correct preoperative diagnosis was made, a brief case-record of each is given here.

Case 12.—A boy, aged 2 years, was admitted to St. Bartholomew's Hospital on Feb. 16, 1942, having passed blood in his motions. The mother had noticed bright blood in a loose motion three weeks previously. The child appeared well otherwise, with no vomiting or pain. Thereafter he passed a dark stool daily, started to go off his food, and complained of lassitude. Three days before admission he started to improve and passed more normal motions.

Examination.—The child was well built but pale and irritable Abdomen, nothing abnormal discovered: sigmoidoscopy normal. Temperature went up to 100°F and pulse-rate varied from 100 to 120. Hæmoglobin 34%, falling later to 29%; next month it rose to 58%. No pathogenic organisms isolated from stools. Heterotopic gastric mucosa in a Meckel's diverticulum was suspected, but the mother did not agree to operation.

The patient returned on May 23, 1942, with recurrent hæmorrhage; his health had deteriorated; Hb 47%, pulse-rate 120, temperature normal.

Operation.—On May 27 a laparotomy was performed, and a large Meckel's diverticulum situated 9 in. from the ileocæcal valve was removed. The specimen was sectioned by Dr. Cuthbert Dukes, who found large numbers of gastric glands with both pepsin-secreting and acid-secreting cells. There was a small nodule of tissue resembling pancreas. The specimen was presented to the Royal College of Surgeons.

Case 13.—A male, aged 19, was admitted to hospital on Aug. 20, 1941, passing black motions. In 1930 he had fallen off a wall, and two days later had passed black motions for a fortnight. Diagnosed as traumatic intestinal hæmorrhage at St. Bartholomew's Hospital Six months later he had had a shorter attack after eating crackling on roast pork. In 1938 he had again been investigated for abdominal pain and dark motions. Since then he had suffered three or four attacks of melæna a year.

Examination.—Pale, nothing abnormal found. Sigmoidoscopy, barium examination, and gastroscopy all normal.

Operation on Sept. 20, 1941, revealed a small Meckel's diverticulum 2 ft. from the ileocæcal valve and adherent to the mesentery with several enlarged lymphatic glands nearby. Section of the diverticulum by Dr. Dukes showed heterotopic gastric mucosa with ulceration.

Follow-up.—Seen on Aug. 25, 1942, patient was very fit and serving in Royal Air Force.

ACUTE SURGICAL CONDITIONS DUE TO MECKEL'S DIVERTICULUM

Case no.	Sex	Age (yrs.)	Clinical findings on admission	Provisional diagnosis	Operative findings	Result
1	M	31	Acute abdominal pain; nausea, vomiting; tenderness not localised	Appendicitis	Gangrenous M.D.	Recovery
2	M	11	Abdominal pain; tympanites; absolute constipation 3 days	Intestinal obstruction	M.D. twisted round and obstructing gut	Death
3	M	4	Abdominal pain 48 hr.; vomiting; mass in right side; blood and mucus present per rectum	Intussusception	Intussusception with M.D. at tip	Death
4	M	64	Abdominal pain; vomiting for days	Intestinal obstruction	Small intestine obstructed by M.D. attached to anterior abdominal wall	Recovery
5	M	10	Abdominal pain few hours; vomiting; shock; mucus only per rectum	Intussusception	Intussusception with M.D. at tip	Recovery
6	F	36	Abdominal pain 24 hr.; no vomiting; 2 months pregnant; tender right iliac fossa	Appendicitis	Inflamed M.D.	Recovery
[illegible]	M	23	Abdominal pain 3 days; vomited continuously; hiccups; ileus	Intestinal obstruction	Small intestine obstructed by M.D.	Death
8	M	6	Abdominal pain 2 days; no vomiting; tender in right side of epigastrium	Appendicitis	M.D. with peptic ulcer at tip; subacutely inflamed appendix	Recovery
9	M	44	Abdominal pain; no vomiting; tender in both iliac fossæ	Appendicitis	Inflamed M.D. containing gastric mucosa; subacutely inflamed appendix containing 2 carcinoid tumours	Recovery
10	M	30	Recurrent attacks of severe melæna; two blood-transfusions; barium enema showed no abnormality	Duodenal ulcer	Leiomyoma of M.D. adherent to another loop of ileum	Recovery
11	M	73	Acute pain around femoral canal; constipation	Strangulated hernia	Littré's hernia with gangrenous diverticulum	Recovery

M.D. = Meckel's diverticulum.

Sir Gordon Gordon-Taylor also informs me that he has had 1 case of bleeding from an ulcerated Meckel's diverticulum. Schullinger and Stout (1934), reviewing this complication in the light of 68 previously recorded cases, wrote: "Sudden severe pain in the lower abdomen with rigidity, signs of diffusing peritonitis, fever and leucocytosis, especially in children should lead to suspicion of Meckel's diverticulum. Cryptic intestinal bleeding should make one suspect Meckel's diverticulum as a possible source."

5. A *foreign body* is occasionally met with in an inflamed Meckel's diverticulum, and has probably the same significance as a foreign body in the inflamed appendix. Case 6 presented an acutely inflamed diverticulum which on being cut open was found to contain a rolled portion of tomato skin.

6. *Neoplasm* is a rare complication, but 1 is recorded in this series. The leiomyoma reported here had caused repeated melæna, which on more than one occasion had necessitated blood-transfusion, a bleeding duodenal ulcer being suspected. The patient was admitted with Hb 32% and required four pints of blood before laparotomy could be undertaken. The tumour was well encapsulated and very vascular, but with no evidence of malignancy. This patient replied to an inquiry on Oct. 21, 1946, that he was fit and well, weighed 12 st., and had suffered no further attacks of bleeding.

7. *Aberrant pancreatic tissue* occurs in many sites in the abdomen, but Hunt and Bonesteel (1934) could find only 13 recorded cases in which it had been demonstrated in Meckel's diverticulum. They added a 14th case in which the presenting symptom was acute lower abdominal pain unassociated with vomiting, tenderness, or rigidity. It is interesting to speculate whether the pancreatitis seen in these cases is primary or secondary to an inflammation of the diverticulum; possibly such tissue could be involved in mumps.

CHRONIC SYMPTOMS

All the above complications manifest themselves in some form of acute abdomen, and I have found no record of a Meckel's diverticulum causing chronic or subacute abdominal symptoms. This is all the more surprising when it is remembered that any diverticulum of a hollow viscus is a potential source of pain if it is distended. Spriggs and Marxer (1925–26), in their comprehensive review of intestinal diverticula, state that duodenal and jejunal diverticula may give rise to definite and sometimes distressing symptoms. "The cause of the symptoms is probably mainly stretching of the walls of the pouch by distension with food or irritation by either acid or putrefying material." It is remarkable therefore that the most constantly present diverticulum of the small intestine (Edwards 1939) should not have been described as producing symptoms similar to a diverticulum of the duodenum or jejunum. The following case illustrates the type of clinical picture which may be presented:

Case 14.—A leading seaman, aged 27, reported to a Naval sick-bay complaining of pain in the lower abdomen which had troubled him intermittently for six months. He pointed to a spot three finger-breadths above the symphysis pubis as the site of the pain and said that it was occasionally severe enough to wake him at night.

Examination.—He was a well-built man with tongue clean and moist and abdomen moving normally on respiration. On palpation a vague swelling could be made out just to the right of and below the umbilicus, and on firm pressure the pain could be reproduced. There was no hernia; patient had never vomited during an attack and did not have constipation or difficulty of micturition. *Urine:* sp. gr. 1·016; acid reaction; no albumin, sugar, or ketones present. Blood-count: red cells 4,810,000; Hb 104%; colour-index 1·08; white cells 6400 per c.mm. (polymorphs 66%, lymphocytes 29%, monocytes 3%, eosinophils 2%). Wassermann and Meinicke reactions negative.

Straight radiography of the abdomen revealed abnormality. At barium-meal examination the stomach duodenum were seen to have normal outlines; no evid of diverticulum was detected; the meal passed norm through the intestine.

Operation.—As the patient continued to have intermi attacks of pain and discomfort, it was decided to perfo laparotomy, the provisional diagnosis being a mes cyst. The abdomen was opened; there was no exce free fluid, the appendix appeared healthy, and there no adhesions. The stomach and duodenum appeared no and no diverticulum of the latter was present; pan normal on palpation; no evidence of a mesenteric A tubular Meckel's diverticulum, with engorged v coursing over its apex, was discovered about a foot fro ileocæcal junction; and, as this would lie naturally in app mately the position at which the patient complained o pain, it was decided to remove it. A crushing clamp placed across its base, and it was excised; the ileum narrow at this point and, as the removal of the divertic decreased its breadth even further, a side-to-side anasto was performed to ensure that stenosis was not prod The appendix was removed and the abdomen closed.

Progress.—Convalescence was uneventful. Eighteen after operation he was discharged from hospital with a sou healed wound and complete relief from his previous pai discomfort.

A month later he was having some trouble with flatu but four months later he was completely free from hi complaints.

Pathologist's Report (Dr. W. W. Woods).—"Me diverticulum; no gastric mucosa; no pathological ch A bell-shaped piece of intestine and thus a characte Meckel's diverticulum. It has been turned inside out fixed in this position. It measures about 1·5 cm. in diam The mucosa looks normal, being grey, velvety, and th up into ridges. No sign of a different sort of mucosa in part. No congestion. No ulceration. Serosa is partly partly dull red. Wall not thickened; mucosa, submucosa muscularis are each about 0·05 cm. thick.

"The diverticulum has the structure of normal inte Its villous mucosa is everywhere the same. There i gastric mucosa. The occasional epithelial cells with eo philous cytoplasm in the deeper glands are the normal Apart from the normal areas of lymphoid tissue, the conne tissue of the mucosa contains eosinophil leucocytes, lym cytes, and plasmacytoid cells, but they do not appear in greater numbers than are found in normal intestinal mu The moderate degree of congestion of submucosa and serosa and the few focal hæmorrhages occurred during operation. Thus there is no inflammation, nor strangula nor any other pathological change."

A thorough investigation of this patient was m before and during operation, and it could reasonabl claimed that most of the other causes for these attac abdominal pain had been eliminated. After exci of the diverticulum the patient was completely reli of his symptoms; hence it appears very probable his attacks of pain were due to intermittent disten of his diverticulum, its inability to empty, or narro of the small intestine at this point. The narrowin "coarctation" of the ileum opposite the divertic may have been responsible for its inability to em properly. It might have been wise to resect the seg of intestine rather than amputate the diverticulum then short-circuit the coarctation as was done in this c

This is only a single case-record, but it suggests th the possibility of such a condition were kept in m others might be found. It provides yet another g reason for looking for a Meckel's diverticulum w every appendicectomy is performed, and it is preci in those patients with a not too clear-cut clinical pic of appendicitis that the condition is most likely to encountered. Though the diverticulum was not sh at barium examination in this case, it is someti possible to show its presence, as in Rousseau and Mart (1943) patient. I do not agree with Greenblatt et (1936) that all Meckel's diverticula encountered laparotomy should be removed as a routine.

analysis of the last 11 cases of acute abdomen in a Meckel's diverticulum was the causal factor to the hospital shows examples of practically known complication, and confirms the opinion vious writers on the subject that the correct is is rarely made before operation.

commonest situation for this developmental error in. from the ileocæcal valve, but it has often been vered 12–36 in. from the end of the ileum; therefore, the whole terminal 3 ft. of ileum is inspected, it be overlooked.

SUMMARY

kel's diverticulum occurs in 1·3% of people and is in the ileum 18–36 in. from the ileocæcal valve.

te abdominal symptoms are caused by the diverti-, and the pathogenesis of these has been investigated consecutive cases. Two additional cases presenting a are described.

ute or chronic abdominal symptoms were caused the diverticulum in 1 case and its mechanism is ed.

ckel's diverticulum should be looked for more often more carefully, especially in laparotomies where the abdominal organs do not appear sufficiently mal to explain the signs and symptoms.

is a pleasure to acknowledge the assistance given by rdon Gordon-Taylor and Mr. Rupert Corbett in providing ation about their cases, to *Dr. W. W. Woods for the* logical report, and not least to Miss D. A. Fern, chief of the record department, King's College Hospital.

DETERMINATION OF HÆMOGLOBIN

II. THE HALDANE HÆMOGLOBIN STANDARD

COMPARED WITH IRON AND GASOMETRIC ESTIMATIONS

J. KING M. GILCHRIST I. D. P. WOOTTON

THE Haldane-Gowers method for estimating hæmoglobin has been widely used in this country for many years in determining normal English hæmatological values and assessing nutrition. It is therefore desirable that the results obtained by this method should be capable of comparison with the results of other methods in other countries, but before this can be achieved it is necessary to be certain what the Haldane standard represents in terms of hæmoglobin.

The solution of carboxyhæmoglobin which Haldane (1901) adopted as a standard was equal in colour to a 1% dilution of blood which had an oxygen capacity of 18·5 ml. of oxygen/100 ml. as estimated by the Haldane gasometric method. The application of Hüfner's (1894) factor (1 g. of Hb=1·34 ml. of O_2) converts 18·5 ml. of oxygen to 13·8 g. of hæmoglobin (Hb). Hence it has been generally accepted that 100% on the Haldane scale is equivalent to 13·8 g. of Hb/100 ml.

More recently the method of standardisation has been altered, colour tubes being defined in terms of colour, and only indirectly in terms of oxygen capacity.

B.S.I. COLOUR STANDARDISATION

The standardisation of the Haldane Hb method—British Standard 1079 (1942) (Donaldson et al. 1943)—was undertaken to remove as far as possible the non-personal error in the Haldane hæmoglobinometer. In the British Standards Institution (B.S.I.) specification, limits of accuracy were set for each part of the apparatus—colour tube, dilution tube, and pipette. The limits were chosen to be acceptable to both user and manufacturer: sufficiently narrow not to add appreciably to the experimental error, and wide enough to allow economic production by the manufacturer. For the colour tube a colour definition was adopted. The optical absorption of the completed tube was specified rather than the chemical properties of the Hb solution. This course was taken because the primary function of the colour tube is to act as a colour standard, and because colour can be measured as accurately as oxygen or iron. There also follows the advantage that a colour tube can be tested at the last stage of manufacture and at any time in the course of its life.

The maintenance of the colour standard at the National Physical Laboratory (N.P.L.) has now been going on for about five years. On the whole, the methods of colour specification adopted in British Standard 1079 have been found satisfactory in practice. It has been possible to make calibrated colour tubes generally available at reasonable cost. With the present steady improvement in colour-measuring apparatus, both visual and photo-electric, an accuracy corresponding to $\pm{}^1/_2$% in Hb concentration can be realised both in the maintenance of the standard and in the routine testing of the tubes for distribution. The unexpected permanence of the colour tubes also helped considerably to reduce the work connected with maintenance. These tubes have the reputation of sometimes fading badly, and certainly we have come across some examples of discoloured tubes of older manufacture; but, since the standardisation, none from the current commercial production has been found to fade in this way. In the course of the colour-tube testing at the N.P.L. some 20 tubes have been measured and subsequently remeasured after being in use for an average interval of about 2 years. The average rate of change is 0·2% per year. This performance compares very favourably with that of other colour standards, such as dyed gelatin filters or even some coloured glasses.

OXYGEN AND IRON EQUIVALENT

In the preparation of the colour standard, the oxygen content of a sample of blood was determined by the Haldane blood-gas apparatus, and its colour after conversion into carboxyhæmoglobin was estimated by a photo-electric spectrophotometer. The colour corresponding to an oxygen capacity of 18·5 ml./100 ml. of blood was then standardised. This method of defining the standard followed the usual practice for making colour tubes; and comparisons with some older tubes, notably one belonging to Dr. C. Price-Jones with which he carried out work on hæmatological standards, afforded confirmatory evidence that the new standard was in agreement with Haldane's original definition.

For some time, however, evidence has been accumulating which suggests that this standard colour represents more than 13·8 g. of Hb. Surveys of the values of normal English males in which an equivalent standard was used—e.g., Price-Jones et al. 1935—gave significantly lower results than those in which other methods for estimating

TABLE I—SCHEME OF INVESTIGATIONS CARRIED OUT DURING TWO SESSIONS AT DIFFERENT CENTRES

Session	Year	No. of samples	Donors	Investigations at:			
				P.M.S.L.	*Cardiff*	Oxford	*N.P.L.*
1	1945	11	Normal adult males	Fe analysis O_2 capacity	O_2 capacity	Fe analysis O_2 capacity CO capacity	*Spectro*-photometer, colour comparator
2	1946	10	Normal adult females	Fe analysis O_2 capacity CO capacity	O_2 capacity	..	Spectrophotometer, colour comparator

Hb were used—*e.g.*, *Jenkins and Don (1933)*—and normal figures from the U.S.A. and other parts of the world agreed more closely with the latter observations (Wintrobe 1942).

It was also observed independently by two of us (E. J. K. and R. G. M.) that estimations by the Haldane method and by photo-electric methods standardised by iron determination suggested that commercial Haldane standards, at any rate, represented more Hb than supposed.

These results suggested that there was need for a more authoritative determination of the Hb equivalent of the standard. The 1942 standardisation experiment was designed on too narrow a basis (one blood only) to give a generally valid relation between oxygen and colour. Its primary purpose was not to establish this relation but to transfer the fundamental definition from oxygen to colour. All that was required, therefore, was that it *should be more accurate than the commercial methods* for producing colour tubes, which it undoubtedly was. When the colour definition and a technique for the production of accurately calibrated tubes had been established, the task of linking colour with oxygen an iron could be undertaken more advantageously.

Macfarlane and O'Brien (1944) and King et al. (194 carried out an extensive determination of this relationshi with 49 and 20 *bloods respectively*. The result was th the B.S.I. standard was found to be equivalent to 14·7 of Hb on an oxygen basis, and 14·8 g. of Hb on an iro basis. This difference from 13·8 g. was considered t large to be explained on the grounds of experiment error, though no adequate explanation for the discrepan was offered.

In these latter experiments the colour was determin by the usual hæmoglobinometer colour tube and dilutic tube. *Macfarlane (1945) has shown that* with so observers the personal error in colour matching exceeds the calibration errors, and that the colour measur ment was probably for this reason more unreliable th the oxygen or iron estimations. Following a suggesti put forward by him, the work has been repeated wi the substitution of the N.P.L. colour-measuring equipme for the Haldane Hb method.

TABLE II—COMPARISON OF HÆMOGLOBIN CONTENTS OF 21 NORMAL BLOODS DERIVED FROM IRON AND GASOMETRIC DETERMINATIONS WITH THE HALDANE VALUES AS MEASURED IN COLOUR COMPARATOR

The arrangements of this redetermination and i results are described below.

EXPERIMENTAL

General Organisation.—The work was carried o *during a large-scale investigation* into the accuracy different methods of Hb determination, conduct simultaneously *at the Postgraduate Medical* School London, the University of Cardiff, the Radcliffe Infirmar Oxford, and the National Physical Laboratory. Veno blood was withdrawn from subjects at Oxford, a samples were distributed by post to the other centr considerable care being taken to make sure that t samples were truly representative of the original bloo Simultaneous determinations at the various centres we then carried out; these usually began within 24 hou *of taking* the blood. Generally one or two samples of blo were dealt with during each week of an experiment session. Further details are given in table I.

Briefly, iron was determined by titration with titano chloride (*Delory 1943*); *oxygen capacity* was determin according to the method of Van Slyke and Neill (1924 and carbon *monoxide* capacity, both *before* and aft preliminary reduction, was measured.

Preparation of Solutions.—Solutions of as many as different Hb derivatives were prepared. For the prese purpose, however, solutions of carboxyhæmoglobin we prepared as follows:

With calibrated pipettes and volumetric flasks, dilutions the blood *sample* (1·0% and 0·5%) were made with 0·01 ammonia.

The *solutions* were then placed in conical flasks a thoroughly gassed with the commercial coal-gas suppl since preliminary experiments had shown that commerci coal-gas (tested in parallel with pure carbon *monoxide*) d not introduce an appreciable error.

After being gassed, the solutions were preserved in stopper bottles; *if a* delay of more than an hour elapsed between t preparation and colour measurements, *the solutions* we regassed immediately before the measurements were mad

RESULTS

each blood sample the following determinations obtained :

1) The iron content in mg. of Fe/100 ml. of blood.

) The oxygen capacity in ml. of O_2/100 ml. of blood, and carbon-monoxide combining power, both before and after tion, in ml. of CO/100 ml. of blood.

figures were then converted into g. of Hb/100 ml. d with the conversion factors given by Hüfner (1894) , Hb contains 0·334% of Fe, and 1 g. of Hb = 1·34 ml. 0, or of CO.

) The colour as a percentage of the Haldane standard , obtained by comparison of the carboxyhæmoglobin tions with the N.P.L. standards, using a colour parator and a spectrophotometer.

rom (1), (2), and (3), values were calculated of the contion of Hb in g./100 ml. of blood, corresponding to % on the Haldane scale.

table II are shown the iron and oxygen equivalents of B.S.I. standard for each blood.

e colour was also determined on the spectrophotometer complete absorption curves throughout the spectrum for blood. The mean curve for the males and females is n in the accompanying figure, which includes a comparison other measurements by Kennedy (1927), Newcomer 19), Haurowitz (1926), Heilmeyer (1932), Race (1940), Jope et al. (1943).

rom an absorption curve the value on the Haldane scale be derived by calculation. This can be done by using the ption at one wave-length only, but in this instance a od of calculation which gives an over-all result for the plete range of wave-lengths was used. The calculations long and were only carried out for the means of the male female groups. The results are shown in table III.

he oxygen and iron analyses at Oxford have been omitted calculation of the final means, since these analyses only carried out for the first group of male bloods.

he results as measured by spectrophotometer and comtor are in good agreement, and the average for the two ruments has been taken for the final results.

ale–Female Difference.—There is no evidence of any matic difference between the male and female lues. The comparator showed a difference of about 1%, t this was not confirmed by the spectrophotometer.

TABLE IV—NORMAL HÆMATOLOGICAL VALUES (MALES)

Observer	Hb (g./100 ml.)	Red cells (million/ c.mm.)	P.C.V. (%)	M.C.V. (c.μ)	M.C.H. (μμg.)	M.C.H.C. (%)	Remarks

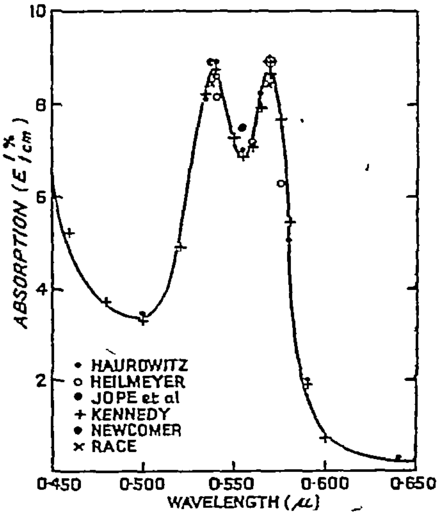
King et al. (England) 1944	16·0	..	..	..	..		Hb by direct iron estimation
Wintrobe (U.S.A.) 1942	16 0	5·4	47 0	87 0	29 0	34 0	Composite "normal" figures for men

DISCUSSION

From the foregoing results it now seems to be established that the B.S.I. Haldane-Gowers Hb standard is quivalent to significantly more Hb than was originally pposed. If iron determination is accepted as the most liable method for estimating Hb, the standard is equivalent to 14·8 g. of Hb. This result, obtained on 21 blood samples by independent determinations in two different laboratories, agrees almost exactly with the previous results of Macfarlane and O'Brien (1944) on 49 samples, and of King et al. (1944) on 20 samples. In the present investigation the colorimetric determinations which form the essential link between the B.S.I. standard and the iron determinations were made with the most precise instruments available in this country, and not, as in the previous work, with the Haldane hæmoglobinometer.

The oxygen-capacity determinations agree less closely with the previous work. Macfarlane and O'Brien (1944) obtained, on the basis of oxygen capacity, an equivalent value for the standard of 14·7 g. Thus the iron and oxygen determinations were in good theoretical agreement. It is true that there was a good deal of variation in the iron/oxygen relationship from one blood sample to another, and from one group of subjects to another. This variation was thought to be due to technical errors, changes in technical ability or procedure during the work, and, possibly, to a sex-difference in the relationship of iron to oxygen capacity.



Absorption curve of carboxyhæmoglobin. Optical density of a 1 cm. layer of a solution containing 1 g. of Hb per 100 ml. Hb was determined by iron analysis (1 g. of Hb contains 3 34 mg. of Fe).

In the present series, however, the oxygen-capacity determinations, made by the same method but in three different laboratories, agree fairly closely to the mean figure of 14·4 g. of Hb as the equivalent of the standard. Thus there are two discrepancies to explain: (1) the difference of 0·4 g. (or 2·7%) between 14·8 g. as determined by iron estimation and 14·4 g. as determined by oxygen capacity in the present series; and (2) the difference of 0·3 g. (2%) between the present equivalent determined by oxygen capacity and that of Macfarlane and O'Brien (1944).

It must be admitted that neither the iron nor the gasometric method is absolutely accurate. Variations in technique, in reagents, and in apparatus may, in either case, lead not only to variation between results but also to consistent errors that may affect the mean of a series of results. Such errors may explain part of the observed discrepancy between iron and oxygen figures in the present series. Part of the difference may well be due to the presence of inactive Hb in certain blood samples, which would therefore give a low oxygen capacity per unit of Hb iron. It may be significant in this respect that the CO capacity estimated after reduction of the Hb sample is very close to the theoretical figure for the oxygen/iron ratio (preliminary reduction converts any inactive Hb into a form which is capable of combining with carbon monoxide).

As regards the oxygen-capacity estimations of Macfarlane and O'Brien (1944) the reason for the difference from the present figure is not clear. It seems unlikely that the latter, derived from three independent sources in good agreement, is at fault. It is also unlikely that the normal blood samples examined in the 1944 series differed qualitatively from the present series to a degree likely to explain the difference. It must be assumed that, for some unknown reason, the previous oxygen-capacity determinations were too high, or the iron results too low. Since the iron results agree well both with those of King et al. (1944) and those of the present series, it seems probable that it was the 1944 oxygen method that was at fault to the extent of 2%.

A sex-difference in the relationship between the colour, iron content, and oxygen capacity of Hb was suggested by Macfarlane and O'Brien (1944) and Bell et al. (1945) but denied by Gibson and Harrison (1946). No evidence of a significant sex-difference of this sort was found in the present investigations; hence no separate definition for the standard is required for male and female blood. The problem that now arises is to decide whether the standard, for purposes of reference and calculation, should be taken as 14·8 g. or 14·4 g. of Hb. The latter is likely to be the figure derived in any future work if the Van Slyke oxygen-capacity method is used, as it usually is in the standardisation of other Hb methods. In terms of Hb mass, however, this figure is probably too low, since by iron determination 14·8 g. of Hb is obtained and 14·7 g. by CO capacity after reduction. The figure given by the iron determination, therefore, seems to be the correct one to adopt.

Such an adoption would bring the normal English hæmatological values into close agreement with those accepted in the U.S.A. Table IV shows the figures obtained by Price-Jones et al. (1935), in which they assumed that 100% of their standard was equivalent to 13·8 g. of Hb. Since it has been found that this standard has very nearly the same value as the B.S.I. standard, it is permissible to recalculate these normal values, assuming that the standard actually represented 14·8 g. When this is done, the results become very similar to those given by Wintrobe (1942) as representative of the U.S.A.

The mean figures given for red-cell count, and mean corpuscular volume for normal males, both in England and the U.S.A., are almost identical; hence the supposed difference in Hb content has always been difficult to explain. It is true that the English standard in these recalculations is based on iron, whereas most American figures are based on oxygen capacity, which may be relatively lower. Against this, however, must be set the fact that the English surveys have used the Haldane-Gowers Hb method, and it has been shown (Macfarlane 1945) that even the most experienced observers read, on the average, 4% too low by this method, a tendency that would more than compensate any difference between iron and oxygen standardisation.

As regards the difference of 4·4% between Haldane's original definition of his standard and the present value, it is probable that it can be explained almost entirely by the lower results given by the Haldane gasometric method as compared with the modern Van Slyke apparatus. Bierring et al. (1936) found a mean difference in the results of the two methods of 1·2 volumes %, an even greater difference than exists between the two definitions.

SUMMARY

The hæmoglobin values of 21 normal bloods have been measured by iron analyses and gasometric determinations carried out simultaneously at several centres. By means of the N.P.L. colour comparator and a photoelectric spectrophotometer, the hæmoglobin contents of these bloods have also been measured on the Haldane-Gowers scale.

The B.S.I. standard tube (100% Haldane) is not equivalent to 13·8 g. of hæmoglobin per 100 ml. of blood but to 14·8 g. when measured by iron analysis, or 14·4 g. when measured by oxygen capacity.

The reasons for this discrepancy are discussed.

Normal English hæmatological values, when recalc lated with the new value for 100% Haldane, come in line with those published in other countries, notab the United States.

This investigation has been carried out for the Medi Research Council's subcommittee on analytical metho The expenses incurred were partly defrayed by a gr from the Medical Research Council, to whom grate acknowledgment is made.

Our thanks are due to Dr. C. R. Harington, chairman the subcommittee on analytical methods, for much valua advice; Dr. Q. H. Gibson and Miss K. Glaser, Miss Quel Mr. A. F. Hoffler, and Mr. W. Weedon for valuable assistan The colour measurement of the carboxyhæmoglobin solutic was carried out at the National Physical Laboratory on beh of the Medical Research Council.

DISSEMINATION OF HÆMOLYTIC STREPTOCOCCI IN AIR

LEONARD COLEBROOK
M.B. Lond., F.R.C.O.G., F.R.S.
MEMBER OF SCIENTIFIC STAFF, MEDICAL RESEARCH COUN

W. P. DALLAS ROSS *
M.B. Camb.

From the Burns Unit at the Birmingham Accident Hospita

THE events which initiate an epidemic seldom come light. The following story describes events which mig well have formed the starting-point of at least a ser of cross-infections, but thanks to prompt action th did not. The story is also of interest for its bearing the mechanism of such cross-infections in surgical wa and as illustrating the value of the bacteriologi laboratory in controlling such infections.

It is our practice in this unit to dress all burns in specially ventilated dressing-room or, occasionally, in similarly ventilated saline-bath room; they are nev exposed in the open wards (Bourdillon and Colebro 1946). This, combined with a strict dressing techniq and the local application of penicillin, has almo eliminated added infections by hæmolytic streptoco for $2^1/_2$ years (Colebrook et al. 1947). It is necessa however, to be constantly on the watch for the occasio reappearance of these infections and particularly detect the streptococci should they at any time be prese in the air of the dressing-station. For this purpose it part of our routine to expose a blood-agar plate (we c it a "settle" plate) whenever patients are being dress Sometimes a more severe test for the purity of the Sometimes a more severe test for the purity of the is made with the large-model Bourdillon slit-sampl (Medical Research Council 1947), which can suck as 20 c. ft. of air a minute on to the surface of a

* Receiving a whole-time grant from the Medical Research Counc

streptococci are very seldom present in the none were found on 76 settle plates exposed between 23, 1946, and Jan. 7, 1947. On Jan. 8, 25, and 27 on Feb. 1, however, single colonies of streptococci obtained on the settle plates, and on Jan. 30 the ampler revealed a heavier contamination of the air olonies on one plate). During this period they were grown in small numbers from the air of the saline- room on one occasion (Jan. 23) and from the en's ward of the unit (Jan. 31).

equent investigation of these air-borne streptococci Dr. V. D. Allison at the Central Public Health atory, Colindale, showed that two distinct types present on different occasions. Thus, the strepto- recovered on Jan. 8, 25, and 27 and on Feb. 1 the air of the dressing-station and on Jan. 23 from air of the saline-bath room were all type-I strains, as those recovered by the slit-sampler on Jan 30 the air of the dressing-station included a few of type I strain on four of the plates, and a second type, p 19," on one other plate. This second type was recovered from the air of the children's ward on 31.

INVESTIGATION OF SOURCE OF STREPTOCOCCI

e existence of two distinct types was not known at the time of the investigation; nor were we of any probable source among the patients or the nnel of the unit. Throat swabs of everyone who been in the dressing-station or saline-bath room when tococci were recovered from the air yielded none of organisms; and all the 56 burns under treatment streptococcus-negative, though one child had given ative swab (later found to be an Imp. 19 strain) Jan. 8, 11, and 13. Three subsequent swabs from child taken during and after local treatment with cillin had been negative on Jan. 15, 22, and 30. source of her infection could not be traced.

nce this child's strain was identical with those grown large numbers from the air of the dressing-station Jan. 30, and only when this child was in the room, it s highly probable, indeed almost certain, that the a were in some way disseminated in the air during child's dressing, notwithstanding that a swab from child's granulating wound did not yield any strepto- on this occasion. The most likely explanation is the child's bedding became contaminated with olytic streptococci when her wound was infected that organism (Jan. 8, 11, and 13); the blankets possibly also other bedding) were not changed after organisms disappeared from the wound under cillin treatment; from these infected blankets, and/or r bedding, the streptococci passed to the crêpe dages covering the burn, and during the removal of crêpe bandages they were scattered into the air the dressing-station. Direct contamination of the of the dressing-station from the child's bedding bed-jacket could not have happened, since these been removed or covered with sterile sheets before came into the dressing-station.

The suggestion that the child's bedding was the ulti- source of the Imp. 19 cocci found in the air was merely hypothetical; it is supported by the fact , though moist swabs taken direct from the bedding ed no streptococci, these organisms were recovered slit-sampler plates when the child's blankets were en near the machine, on two separate occasions, the same day as she was in the dressing-station n. 30). On the day following exposure of her burn to heavily contaminated air of the dressing-station, the p 19 strain was again found on the child's burns. ppily it did not infect either of the two patients who followed her, after an interval, in the dressing-station on Jan. 30.

The type-I streptococcus found in the air on five occasions appears to have had a totally different origin. On Feb. 1 Mr. A, the surgeon who had been doing all the dressings, remembered that he had a small scabbed-over abrasion on his elbow, dating from before he joined the burns unit on Jan. 1, 1947. It had given him no trouble and, so far as he was aware, had remained perfectly dry throughout January. However, on Feb. 1 Mr. A removed the scab and cultivated the trace of serous fluid beneath it. It gave a pure culture of hæmolytic streptococcus, type I. On Feb. 2 he swabbed his waistcoat and shirt, and on Feb. 3 his jacket and the skin of his forearm and neck. The waistcoat swab yielded hæmolytic streptococcus type I; the others were negative. The elbow lesion had been treated with penicillin cream on Feb. 1 and promptly healed.

How did the streptococcus reach the air of the dressing-station from the scabbed-over lesion on Mr. A's elbow? He had never worn his waistcoat during dressings, and his clothing had always been covered with a sterile gown and canvas overshoes. The gown, however, did not give complete cover, because Mr. A is very tall and the gowns are often imperfectly closed at the back. His forearms were exposed during dressings; so there was opportunity for friction between the forearm skin and his gown. It is also possible that, though we detected hæmolytic streptococci only on his waistcoat by our casual swabbing of a small area with a moist swab, a more efficient method of extracting dust from the clothing, like that used in vacuum-cleaning, might have revealed the presence of streptococci also on his shirt, trousers, &c. (see below). In that case the movement of his garments might well have been responsible for the small number of streptococci isolated from the air of the room. In this connexion it will be remembered that Hare (1941) reported finding hæmolytic streptococci on the clothing of healthy throat carriers.

It is therefore suggested that contamination of the air by this type-I strain was due, in the first place, to imperceptible leakage of serous fluid from Mr. A's lesion, the fluid drying into powdery scales on his forearm and being rubbed off either by the sleeves of his gown or by his clothing.

None of the 42 wounds dressed by Mr. A on the days when his type-I strain was found in the air of the dressing-station or the saline-bath room acquired this organism. This and the similar fact noted in connexion with the Imp. 19 strain of the child were probably due to the constant decontamination of the air of the dressing-station by the forced-ventilation system, by which the air of the room is completely changed every few minutes (Bourdillon and Colebrook 1946).

SUMMARY

Hæmolytic streptococci recovered from the air of a dressing-station were of two types: type I and type Imp. 19.

The evidence suggests that the type-I strain came indirectly from a small scabbed-over lesion on the elbow of the surgeon doing the dressing (perhaps from his clothes); and that the Imp. 19 strain was scattered in the air during the removal of bandages from a burn which was not at the time infected with that organism, the bandages having become contaminated from the child's bedding.

NOTE ON THE DETECTION OF PATHOGENS, ETC., ON CLOTHING BY "HOOVERING"

In 1944 Dr. R. B. Bourdillon suggested to one of us (L. C.) that a slit-mouthed flexible tube fitted to the air-inlet of the slit-sampler would enable us to sample a much larger amount of dust from clothing, bedding, &c.,

than is obtained by merely swabbing it with a moist swab. Dr. Bourdillon also made the appropriate fittings at that time, but we had not previously used it. After the events recorded in this paper we carried out some trials as follows:

(1) Four streptococcal throat carriers, one of whom, A. B., had also a streptococcal infection of an old burn on his leg, gave the following results:

In the case of A. B. "hoovering" bedding, dressing-gown, &c., gave 42 colonies of hæmolytic streptococci, whereas moist swabs of the same articles gave none; but unfortunately these swabs were taken after the "hoovering," so that it is possible, though not likely, that a large part of the contaminated dust had been removed. Of the 42 colonies obtained by "hoovering," 10 were tested for type. All belonged to type II, which was the type present in the patient's throat and on the leg.

Of the other three carriers, C. D., aged 2 years, gave no hæmolytic streptococci by moist swabbing (swabs before the "hoovering"), but 8 colonies were grown by the "hoovering" test. All the 8 colonies were of the Imp. 19 strain present in the child's throat.

Another child, E. F., yielded one colony of hæmolytic streptococci on "hoovering" the bedding, and none by swabbing.

The fourth child gave one colony by swabbing and none by "hoovering."

(2) In the case of 8 other people with negative throat swabs, 5 of whom were working in the wards in more or less close contact with streptococcal infections, one or two colonies of hæmolytic streptococci were recovered by "hoovering" the clothing from 3 but none from the others. Tests by swabbing were not made in these cases.

So far as it goes, therefore, the evidence suggests that "hoovering" clothing, bedding, &c., is much more likely to detect hæmolytic streptococci than moist swabbing, and that it may prove a valuable aid in the future investigation of cross-infections.

We wish to thank Dr. Allison, whose help in the typing of the streptococci made this investigation possible; Dr. Bourdillon, who taught us to use the slit-sampler and suggested the "hoovering" device; and Mr. Michael Hood for technical assistance.

CALCIFEROL IN THE TREATMENT OF CHILBLAINS

S. T. ANNING
M.D. Camb.
TUTOR IN DERMATOLOGY IN THE UNIVERSITY OF LEEDS

CALCIFEROL in high dosage has been widely advertised as effective in the treatment of chilblains. Since this therapy is hazardous unless controlled by estimations of blood-calcium (especially diffusible calcium) and of renal efficiency, it seemed important to assess its effects on chilblains.

The incidence of chilblains during last winter in a group of patients receiving calciferol in large doses for other reasons was determined and compared with the incidence in a group not receiving calciferol.

Material.—The test group (A) consisted of 103 patients (36 men and 67 women) with either lupus vulgaris (92 cases), sarcoidosis (6 cases), tuberculosis verrucosa cutis (3 cases), lupus erythematosus (1 case), or erythema induratum (1 case). Their mean age was 46·3 years (variation 21 to 70) with a standard deviation of 9·2. This group received calciferol daily in tablet form by mouth in doses of 50,000–150,000 I.U. (tab. 'Ostelin,' high potency, Glaxo) for various periods but consistently through the winter months from September, 194 March, 1947 (with four exceptions who took the ta for a shorter time during this period, one for a m one for two months, and two for five months). The r individual doses were as follows:

INCIDENCE OF CHILBLAINS IN RELATION TO TREATME WITH CALCIFEROL

—	Sex	Experimental group A	Control group B	Con gro
No. in group.. ..	M F	36 (35%) 67 (65%)	19 (39%) 30 (61%)	44 (66 (
Total		103	49	110
Mean age (years) .. Standard deviation ..		46·3 9·2	42·4 15 9	43 4 13·1
No. with lupus vulgaris		92 (89%)	45 (92%)	N
No. who had had chilblains before 1946–47 winter	M F	5 (4·8%) 19 (18·4%)	1 (2·0%) 4 (8·2%)	9 (26 (
Total		24 (23·2%)	5 (10·2%)	35 (
No. who had chilblains for the first time in 1946–47 winter	M F	7 (6·8%) 7 (6·8%)	3 (6·1%) 4 (8·2%)	6 (4 (
Total		14 (13·6%)	7 (14·3%)	10 (
Total no. with chilblains in 1946–47 winter	M F	9 (8·7%) 20 (19·4%)	4 (8·2%) 8 (16·3%)	10 (21 (
Total		29 (28·1%)	12 (24·5%)	31 (

Standard error, 8·7

	Mean individual dose (million I.U.)	*Variation* (million I.U.)	Sta devi
Patients with chilblains ..	21·4 ..	2·0–42·9 ..	
Patients without chilblains	22·2 ..	2·8–40·2 ..	

The controls were in two groups: group B consis of 49 patients (19 men and 30 women) with e lupus vulgaris (45 cases), tuberculosis verrucosa c (3 cases), or erythema induratum (1 case); and grou of 110 patients (44 men and 66 women) atten primarily for skin conditions other than chilblain lupus vulgaris. The total control group there consisted of 159 patients, none of whom was gi calciferol.

Results.—The accompanying table shows that 28· of the 103 patients given calciferol developed chilbla and of the 159 patients not given calciferol, 24·5% group B and 28·1% in group C developed chilbla There is no statistically significant difference betw the test and control groups as regards the incidence chilblains. It is thus clear that, in the conditi of this test, a patient receiving calciferol is as liable chilblains as one who is not receiving it.

Comment.—These results suggest that calciferol ineffective in preventing chilblains. Further, calcife appears to have no effect in the treatment of chilbla since chilblains developed and persisted about the sa length of time in all the groups.

As treatment with calciferol in high dosage is n without danger, it would be as well if its use for t purpose were discontinued.

I am grateful to Dr. J. T. Ingram and Dr. F. F. Helli for allowing me to carry out this investigation on th patients.

EACH bed in the new tuberculosis wards at Anlaby Ro Hospital, Hull, has been equipped with a pillow-wirel according to the Hull *Daily Mail* (Oct. 16).

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

The annual meeting was held in Manchester on Oct. 24 25 under the presidency of Mr. GEORGE PERKINS.

Recurrent Dislocation of the Shoulder

H. OSMOND-CLARKE described a capsulorrhaphy recurrent dislocation of the shoulder which he called Putti-Platt operation. This consisted in a wide ach to the front of the joint with division of the oid subscapularis tendon, and capsule. The distal e of the subscapularis tendon was sewn to the bourhood of the anterior lip of the glenoid, and the al portion of the tendon was made to overlap ture line. The coracoid was repaired and the wound

J. C. ADAMS had investigated the results, after years or more, of 114 out of 159 operations for ent dislocation of the shoulder in the Royal Air during 1940–45. He said that 21 recurrences had place after 59 Nicola operations, and 2 after 37 -Platt operations. The intervals before recurrence between four months and five years, averaging -two months. Among 79 shoulders adequately ed, the glenoid labrum was found detached in 69 ndly attached in 10. Adequate radiography of tients revealed a posteromedial defect in the ral head of 56; an anteroposterior view with mb rotated inwards through 60–70° was advised. nge of movement was almost full after Nicola's ion; lateral rotation was often diminished after art's operation, and rather more so after the capaphy. The relatively free range after Nicola's ion was perhaps a factor in recurrent cases, which always show atrophy of the reattached tendon. od results of the other operations were attributed e fibrous tissue formed in the front of the capsule. limited lateral rotation.

A. L. EYRE-BROOK gave a detailed analysis of consecutive cases operated on by the anteromedial ach. These lesions were found: anterior detach- of the glenoid labrum (Bankart's lesion) alone in a posteromedial defect in the humeral head alone a combination of these two defects in 10 cases. detachment of the subscapularis from the lesser sity in 1 case. The bony defect was best revealed ratively by radiography from above with the film axilla and the arm laterally rotated through 70°. graphy often disclosed also a bony subglenoid out- in cases of Bankart's lesion. In cases showing lesion at operation, a modified Bankart's operation performed. In cases not showing this, but having t in the humeral head, multiple osteotomy of the d had been performed (2 cases), and more recently pplication of an iliac graft to the front of the r neck. After operation the arm was bandaged side for four to six weeks. Work was resumed after six weeks. In 12 cases followed for periods of ths to four years, no recurrence had been found.

A. B. PAIN had examined the case-records of 43 ions for recurrent dislocation of the shoulder in nts treated in the Leeds area during the preceding years. Of the patients, 1 had bilateral operations, had two operations, and 3 had as many as three ions each; 6 were epileptic. Among 28 patients seven different types of operations had been ed as follows (recurrences in parentheses): Clair- 1 (1), Henderson 13 (9), subscapularis tenotomy Nicola 12 (4), Bankart 2 (1), capsular plication 1 (0), k 4 (0). Recurrence took place at any time up to years after operation, but in 12 out of 18 instances within a year—in 6 of them within three weeks.

Other Papers

JACQUES LEVEUF, in a paper on the *Treatment of Osteomyelitis Viewed from the Anatomical and gical Basis*, expressed the view that in hæmato- osteomyelitis the first bony lodgment of the coccus is not usually the metaphysis but the hood of the entry of the perforating artery, a cortical abscess forms, with usually a very small sequestrum. Spread is mainly towards the surface, but also along the artery and its branches, producing further cortical lesions and occasionally medullary ones. Professor Leveuf, who has practised plaster-of-paris immobilisation in this disease for twenty years, condemns bone operations in the acute stage, and especially metaphyseal drainage. The soft-tissue abscess should be drained between the fifteenth and twentieth day; formerly the wound was left widely open, but now, with the aid of penicillin, it is closed forthwith.

Prof. S. L. BAKER, in speaking of the *Histology of Callus*, stated that the first sign of bone appeared within the first week in an area of gelatinous œdema in the mass of young connective tissue which invades the hæmatoma about a fracture.

This bone is of a type called woven bone, because of the irregular arrangement of the fibres, which with a connecting substance form the osteoid matrix, in distinction from lamellar bone, in which the fibres have a parallel arrangement Whereas woven bone can be laid down rapidly in connective tissue, lamellar bone forms slowly and can only be laid down on a surface. Woven bone forms about blood-vessels, and so the orientation of its trabeculæ is determined by the vascular arrangement, whereas that of the trabeculæ of lamellar bone is determined by the stresses to which it is submitted. Woven bone is usually replaced slowly by lamellar bone. The formation of cartilage in callus appears to depend largely on movement, being frequent after rib fractures and in animals. Cartilage sometimes forms a ring about the fracture and may result in pseudarthrosis, but commonly it is replaced gradually by bone. Callus is no respecter of the periosteum, often passing well outside it.

In certain rare instances, said Professor Baker, especially fragilitas ossium, there is a prodigious formation of callus which may be taken for sarcoma. Dr. J. F. BRAILSFORD and Mr. B. L. MCFARLAND confirmed this danger.

Mr. ROLAND BARNES reported on 22 cases of *Paraplegia in Cervical Column Injuries*, which he subdivided into (1) flexion injuries (dislocation 8, crush fracture 4, acute retropulsion of an intervertebral disc without bone injury 3), and (2) hyperextension injuries (dislocation 1, injury of arthritic spine 6). He believed that with acute retropulsion of an intervertebral disc cerebrospinal-fluid block called for emergency laminectomy and not merely skull traction. With paraplegia following hyperextension injury of an arthritic spine there was little or no evidence of bone injury. These patients were all more than fifty years old. A complete tear of the anterior common ligament had been produced in 1, and it seemed probable that not only was the stiff extended arthritic spine unduly prone to hyperextension injury, but the cervical lordosis and often associated thoracic kyphosis would aggravate the consequent traction injury to the spinal cord, which seemed a probable cause of the paraplegia. Prof. GEOFFREY JEFFERSON, F.R.S., agreed with what had been said but had an open mind about crediting laminectomy with the improvement which sometimes followed it.

Mr. D. LL. GRIFFITHS advocated the following steps in the *Management of Acute Ischæmia in an Injured Limb*.

(1) Adequate general investigation, including arterial blood-pressure and blood hæmoglobin estimation.

(2) Removal of all possible sources of external pressure.

(3) Attention to the patient's general condition, with special reference to maintenance or restoration of a satisfactory blood-pressure.

(4) Reduction of the associated fracture, if any; this may assist the collateral circulation but should be attempted only once.

(5) Operative exploration of the artery, except in cases of over twenty-four hours' duration in the lower limb, or in cases showing obliteration of both anterior and posterior tibial arteries. Preliminary arteriography is helpful. Complete division demands ligation; incomplete division provides an opportunity for a trial of arterial suture; bruising of a length of artery calls for resection; no operation should be performed on the artery if it is occluded by spasm without any obvious arterial injury.

(6) Paralysis of the cervicothoracic or lumbar sympathetic system by local infiltration.

(7) Other measures to improve the collateral circulation: slight elevation or slight depression of the limb, as suits the patient's comfort; cooling the limb, but without the use of ice; warming the patient; administration of morphine, alkalis, and

penicillin. Tobacco is usually condemned, but alcohol may help.

Mr. JOHN CHARNLEY gave a discourse, illustrated by models, on some of the basic mechanical principles used in the *Reduction and Splinting of Fractures.*

Mr. O. H. CULLEN discussed *Causalgia* on the basis of 24 cases he had seen during the war. Of 17 in which sympathetic block was successfully achieved with 2% procaine ('Novocain'), as shown by peripheral loss of sweating, 14 were completely relieved temporarily. For such, sympathectomy was the treatment of choice; in the 8 patients submitted to it, the results were uniformly good, except that 1 patient, in whom part of the stellate ganglion was spared, was not completely cured. Radiotherapy was less successful than sympathectomy, and was reserved for cases not responding to sympathetic infiltration.

Mr. T. J. FAIRBANK spoke on *Fracture-subluxation of the Shoulder.* Among 115 cases of fracture about the shoulder, he had found 12 with radiologically demonstrable downward subluxation of the humeral head; in 11 of these it was a complication of fracture of the neck of the bone. Clinically a groove could be felt between the acromion and the humeral head, which could usually be abolished by lifting the humerus actively or passively, or by recumbency. In the normal subject little downward subluxation occurred except during anæsthesia, and muscle tone appeared to be the main factor preventing it. At follow-up, a year after injury, the subluxation had sometimes disappeared, but it sometimes persisted for three years or more. Of the patients, 9 had been treated for their fractures with collar-and-cuff slings and 3 with abduction frames. It was suggested that, in the treatment of fracture of the humeral neck, a triangular sling is preferable to a collar-and-cuff, and that if abduction is necessary a plaster-of-paris spica should be used. Sir REGINALD WATSON-JONES considered it important to distinguish between subluxation due to the original violence and that due to diminished muscle tone.

In considering the *Treatment of the Unreduced Pathological Dislocation of the Hip from Septic Arthritis in Infancy*, Mr. A. F. BRYSON excluded patients aged more than twelve months at the time of the acute illness. In most it occurred in the first nine months. His 18 cases were all unilateral, and 15 were operated upon. One underwent an unsuccessful Colonna's arthroplasty. Of 3 treated by osteotomy, 1 secured stability, but the other 2 continued to show progressive shortening, flexion, and adduction. Arthrodesis was much the best procedure. Eleven patients were so treated; bony fusion occurred within a few months in 7 of them, and after subsequent osteotomy in another. Operation should be delayed till the age of twelve or thirteen years, because of the great amount of activity possible till then and because earlier bony fusion is not only difficult to obtain but does not fully prevent subsequent flexion and abduction deformity. Preliminary weight traction has been found of little value in diminishing shortening, but freeing of the upper end of the femur at operation allowed considerable correction of real shortening, which in 1 case was reduced from $3^{1}/_{2}$ in. to 1 in. The denuded bone surfaces were secured with Platt's miniature tri-fin nail. Only 1 patient had complained of pain in the back—eighteen months after an operation performed at the age of fourteen years—but she claimed to have walked 40 miles in a day. Professor LEVEUF advocated arthroplasty in such cases, even although unilateral. Mr. R. I. STIRLING considered that a shelf operation had a place in the treatment, in order to limit shortening before the best time for arthrodesis had arrived.

Miss E. L. WILLIS summarised the *End-results in Fractures of the Femoral Neck* in 192 cases treated in the university department of orthopædics at the Manchester Royal Infirmary, with a death-rate of 8% within three months of injury. Out of 113 patients with subcapital and transcervical fracture, 50 were seen two or more years after injury: 22 had good results and 15 poor; 13 showed avascular necrosis of the femoral head. Of 74 fractures treated by Smith-Petersen nailing, 41 showed radiological union. Of 79 basal and pertrochanteric fractures, 51 were treated by well-leg traction, with union in 43. There were 23 good clinical results among 28 patients examined more than a year after injury.

Reviews of Books

Radium Dosage

The Manchester System. Editor: W. J. Mered
M.SC., F.INST.P., physicist to the Christie Hospital
Holt Radium Institute, Manchester. Edinburgh: E
Livingstone. 1947. Pp. 124. 15*s.*

THIS book presents in one volume a complete do system for mould, intracavitary, and interstitial gam ray radium therapy. By means of dosage tables distribution rules it attempts to solve the three probl of radium therapy: how much radium should be us how it must be arranged; and how long treatment sho last. It is based on papers published since 1 by the staff of the Christie Hospital and Holt Rad Institute, including Ralston Paterson, M. C. Tod, H. Parker, F. W. Spiers, S. K. Stephenson, and W. Meredith. These papers are well known to physi and radiotherapists, and the book will replace thumbed "reprints" in all departments where rad therapy is practised.

Milk and Food Sanitation Practice

H. S. ADAMS, B.SC., chief, Bureau of Environme
Hygiene, Minneapolis; lecturer, School of Public He
University of Minnesota. New York: Commonwe
Fund. London: Oxford University Press. 1947. Pp.
18*s.*

THIS well-written book places the whole questio food protection in a modern setting.

The first section, which deals with milk sanitation, an interesting survey of the steps taken in the United St to improve the quality of market milk, and shows that progress has been made in pasteurisation and its accept by the public. Mr. Adams gives minute instructions the standards of milk production, also devoting a chapte unpleasant flavours in milk and means of avoiding th Arguments against pasteurisation are analysed and demoli The second and shorter section deals more broadly with control, discussing inspection of food, the hygiene of worker, the safety of the water-supply, protection contamination, and the war against the perpetual enemi food—insects and rodents.

The book is a valuable statement of the mo attitude towards food and milk; and is besides a le to us in Great Britain on the rather tiresome subjec how far we lag behind in these matters.

Atlas of Cardiovascular Diseases

IRVING J. TREIGER, M.D., assistant professor of medi
University of Illinois, Chicago. London: H. Kimp
1947. Pp. 180. 50*s.*

IN this atlas the anatomy of the normal heart the pathology of the diseased heart are shown in pho graphs of specimens and in radiograms; and as a the corresponding cardiographic changes are also il trated; moreover, each common disorder of the car vascular system is represented by a case of which h clinical details are given. The study of photograp however good—and those in this atlas are exception good—is not an effective substitute for the examinat of the material itself in the post-mortem room, nor the written matter here take the place of a textbo but in so far as the correlation of first-class radiogr with morbid anatomy, as shown in photographs, help the student to a clear conception of cardiovasc disease, this atlas provides excellent instruction.

Experimental Physiology for Medical Students (ed. London: J. & A. Churchill. 1947. Pp. 290. 18*s.* Prof. D. T. Harris notes that in the six years which have pa since the last edition of his book there have been gr advances in the study of electronics, especially during war years. Students nowadays have a first-hand knowle of radio devices, and he has therefore included in the edition such simple assemblies as are thought to pos definite advantages—for example, a robust micro-amme with simple amplifier instead of a highly sensitive and co galvanometer. This has made it possible to replace the ol experiments on nerve by simple exercises illustrating electrochemical view of the propagation of nerve impul The book remains a standby for the student to use conjunction with his theoretical textbook.

Comprehensive Anti-Anœmia Therapy

'VENTRON'

Capsules

In many instances of microcytic anæmia, especially those associated with nutritional inadequacy, there may be a lack of blood-forming elements other than iron: consequently, it is often advantageous to supplement iron therapy by giving the erythrocyte-maturing factor in the form of desiccated gastric tissue, together with vitamins B_1 and B_2 as general aids to nutrition.

Ventriculin is a stable anti-anæmic substance derived from gastric tissue and is a potent erythrogenic stimulant inducing active hæmatopoiesis with rapid elevation of the red blood-cell count.

A combination of Ventriculin in concentrated form with vitamins B_1 and B_2 and ferrous sulphate is available under the name 'Ventron' in bottles of 50 and 1,000 capsules.

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1

Laboratories: Hounslow, Middlesex *Inc. U.S.A., Liability Ltd.*

Protein-replacement therapy

HEPOVITE

A dry granular preparation of malt and enzyme-hydrolysed liver protein, rich in *natural* vitamins and essential amino-acids.

COMPOSITION

(Each 30 grammes contains)

"Protein" (N x 6.25)	15 grm
Carbohydrate (Maltose)	11.4 grm
Vitamin A	500 i.u.
Vitamin D	50 i.u.
Aneurine HCl	1.0 mg
Riboflavin	2.0 mg
Nicotinic acid	6.5 mg
Pantothenic acid	11.3 mg
Pyridoxine	0.32 mg
Biotin	0.065 mg
Folic acid	0.05 mg
Inositol	8.1 mg

Choline, Calcium, Phosphorus and Iron are also present.

DOSAGE

¼ oz. (7 grms) three times daily is sufficient to provide the necessary protein supplement. Hepovite can be taken on a spoon, sprinkled on food or dissolved in milk, fruit-juices or soda-water.

INDICATIONS

To restore and maintain the nitrogen balance in the presence of tissue destruction and repair, e.g. burns, injuries and post-operative states. To provide a dietary supplement in all cases of nutritional deficiency, pregnancy, peptic ulcer, ulcerative colitis and the toxæmias of pregnancy.

Hepovite is issued in tins of 5 oz. at 9/-★ each. Further details on application to the Home Medical Department, Speke, Liverpool, 19, or 50, Bartholomew Close, London, E.C.1

★ *Prices apply to Gt. Britain and N. Ireland only and are subject to professional discount*

THE LANCET

LONDON: SATURDAY, NOV. 29, 1947

Ambulances

RELIABLE arrangements for moving patients by bulance are an important element in any medical ce. Little is heard of the preparations for the bulance system in the National Health Service, its organisation is being considered.

Ambulance services in this country were largely lgamated during the war, but they have now n restored to their pre-war owners and show tendency to revert to their pre-war standards. Is necessarily a good thing? Ought we not to use opportunity for a fresh approach? In greater don, for example, before the war there were ous ambulance services. The greatest was that the London County Council, operating within the undaries of the county. Outside those impassable undaries there were many small ambulance services ed by the boroughs and the counties. Borough bulances could take the patient from the borough to y hospital but not vice versa, and county ambulances re to be used only for the county hospitals. Rates payment were highly diverse: some ambulances re free, while some had a mileage rate, and the nt proceeding to a voluntary hospital in a L.C.C. bulance had to pay cash down or be taken willy-y to a L.C.C. hospital. Finally there were private bulances—more particularly those of the Joint ommittee of St. John and the Red Cross—which garded all boundaries and charged a moderate fee.

In the new health service the ambulances will presumably be free; so one problem at least will disappear. Indeed, the L.C.C. has already dropped its charge for journeys to hospital when the hospital calls the ambulance. But what of the boundary question? Presumably borough and county boundaries will disappear, for in a national service they will have no significance. Will they be replaced by regional boundaries? Since it has been said that regional boundaries are to be no bar to the movement of patients, presumably ambulances will be able to cross them. Up to this point the new system must of itself be an improvement, provided the larger ambulance services do not acquire a larger bureaucracy to hinder them. But there remains a risk that the present speed of dealing with cases will be accepted as a standard to maintain rather than as a basis for improvement. Despite the somewhat rosy statistics which are published, we have heard doctors complain of interminable delays in obtaining ambulances. Further information would be welcome, but it seems at least to be clear that an hour's delay before the ambulance starts is not unusual at any time of year—particularly at the "peak" hours of midday and evening—and that in winter the delay is often much greater. Admittedly, if the case is one of accident or can be certified as "life or death" an accident ambulance can be called, and this will start more or less at once. But the bulk of patients needing immediate admission to hospital are not in this desperate plight; so, though they may be very ill and the anxiety of their friends and doctor very great, they have to wait—to their medical disadvantage where (in pneumonia for example) active treatment should begin at once. Presumably this is because there are not enough ambulances to go round, and because old ones cannot be replaced. Is it, however, certain that a sufficient expansion is envisaged not only to ensure that patients shall not be kept waiting unduly, but also to meet the added requirements that the National Health Service will bring? There are various concealed requirements which rationalisation of hospital work will reveal more clearly. Thus it is evident that something will have to be done about the patient who needs outpatient treatment but is unable to travel to and from hospital, either because of his physical disability or (in the country) because public transport is lacking. Nowadays such a man either goes without the treatment or is given a hospital bed which could be put to better use. It looks as though the scope of the ambulance service must be enlarged to include the wide use of sitting ambulances, to work in connexion with outpatient departments.

Running a large ambulance service is a technical job which few are qualified to undertake; and it is not for the inexperienced to suggest how these necessary improvements should be made. The county health authorities, however, have great experience, and they are to bear the whole burden in the future. We trust that they are dissatisfied with the present service. and are planning boldly for something better.

Cholera and Hysteria

CHOLERA inspired the first attempt at international regulation of quarantine procedures, and the Egyptian cholera outbreak has revealed the flimsy foundation on which a hundred years of such efforts have been based. Since the first quarantine conference in 1851 those concerned with international quarantine have had a twofold purpose: on the one hand, they have sought to promote measures which would prevent the spread of disease from country to country, and on the other hand they have tried to obtain agreement on an upper limit of severity for such measures, which would prevent unnecessary interference with trade and travel. In the Egyptian outbreak the first of these objectives—the prevention of international spread—seems to have been achieved: for cholera has not so far appeared in any other country west of the Persian Gulf, and further epidemic extension is unlikely now that the incidence in Egypt has declined and the Mecca pilgrimage has been concluded. It is the second objective—the avoidance of undue dislocation of trade and travel—which has not been attained, and the story of the failure can be read between the lines of the official Weekly Epidemiological Record of the World Health Organisation and in the press.

For preventing undue interference with international traffic three things are necessary: (1) there must be early and accurate information about the onset and spread of the epidemic and the measures taken by the country of origin; (2) other countries must refrain from measures beyond the maxima laid down by the International Sanitary Conventions; and (3) the measures taken against the infected country must be promptly reported Though many governments deserve great credit for the way they have fulfilled their obligations, far too many others have failed under one or more of these heads. As regards notification, Egypt was prompt to report the outbreak as soon as it was bacteriologically confirmed; but lack of information about its progress and spread was certainly the reason for some of the excessive measures taken against her. It was also unfortunate that there was delay on the part of British military in notifying the Egyptian authorities of four cases in the Canal Zone—though these in no way supported the original allegation of importation from that zone. Again, some neighbouring countries do not seem to have realised the value of negative official reports as a means of countering false rumours, such as those alleging that cholera had arrived in Greece, Italy, and Turkey. (The excellent reports from Saudi Arabia concerning the pilgrimage were a notable exception.) But a second and greater failure lay in the imposition of control measures far in excess of those described in the conventions. Though the quarantine committee of the World Health Organisation Interim Commission had held a special emergency meeting, under the chairmanship of Dr. P. G. STOCK, and had specifically stated that the measures against cholera laid down in the conventions in force were adequate, certain countries—and not always those most at risk—actually closed their frontiers to all passengers and goods coming from Egypt. The process was a gradual one, in the nature of a vicious circle At first measures within the conventions were imposed, such as medical examination and surveillance of passengers and prohibition of importation of fresh food. Then alarmist rumours and press reports, not always accurate, of what other countries were doing roused public opinion, before which some health authorities seem to have given way. Thus it is reported that Italy eventually decided that arrivals from Egypt by air should be held under observation in a hotel in Ostia; the local inhabitants erected barricades, and the bus containing the travellers was turned back after something approaching a riot. France, after a short interval, abruptly forbade admittance to passengers and even mail from Egypt, not only to her metropolitan territory but to all her dependencies. Greece, after quite reasonably requiring sea and air traffic from Egypt to call at specified places, ended by suspending all such traffic. Austria prohibited the importation of all foodstuffs, not only from Egypt but from eight countries "threatened" with cholera. Other countries prohibited the import not only of foodstuffs but of Egyptian cotton, oblivious of the fact that they had been importing for years jute from Bengal and rice from China and Indo-China—the main endemic and epidemic centres of cholera—without any evil consequences: at one point it was even reported that ships could not be chartered to take to Egypt the Chilean nitrates on which the cro
depend. *In the third place*, many of these measu
taken against Egypt were not communicated prompt
or even at all, to the World Health Organisation
Geneva, as required by the conventions. Hence t
sea and air lines were unable to learn from an offic
central authority what they would be allowed to do.

Cholera has been called, in quite a different sen
the "disease of fear"; and certainly fear of it h
caused incalculable trade and traffic losses whi
were largely needless. The lesson will have to
studied carefully when the time comes for the Wo
Health Organisation to revise the conventions
seems clear, however, that it was not the conventio
that were at fault, and that what we have witnes
was a partial return to the "quarantine of the jung

The Enigma of Hæmophilia

WHY does hæmophilic blood not clot when it
shed? What part of the clotting reaction has fail
and can the defect be remedied by treatment?
completely satisfying answer to these questions
yet been found, but research in many countries
clarified our ideas.

It is agreed that the defect in hæmophilia lies in
failure of conversion of prothrombin to thrombin
the presence of ionised calcium and thrombokinas
the first clotting reaction. Two explanations of t
failure have been most popular. The first, associat
particularly with the researches of FONIO, is that
abnormality lies in the platelets; it is thought th
the blood-platelets are abnormally resistant to d
integration and fail to provide the necessary thromb
kinase. This hypothesis has in the past recei
much support; HOWELL, for example, conside
that there is in hæmophilia an inherited defect
the platelets or of the megakaryocytes from whi
they are derived. The second explanation invoke
deficiency in the plasma of thromboplastin (throm
kinase), the platelets being normal. As long ago
1905 SAHLI noticed that hæmophilic blood will c
promptly if a small amount of normal plasma
added, and in 1927 FRANK and HARTMANN[1] und
lined this observation by pointing out that t
coagulation-time of hæmophilic blood can be restor
to normal by mixing with normal plasma. PAT
and TAYLOR,[2] and BENDIEN and VAN CREVEL
isolated globulin fractions of plasma that had t
restorative property; and in 1939 HOWELL,[4] abando
ing the platelet hypothesis, stated that these resul
provide real evidence for the view that blood plas
normally *contains a specific substance* that accelerat
the clotting process, and that this substance is defici
in the plasma of hæmophilic patients. HOWE
proposed the name "plasma thromboplastin" f
this substance. It is essentially the same
MORAWITZ's "thrombokinase"; but this nam
suggests a protein substance of enzymic natur
whereas HOWELL was able to show that thromb
plastin can be freed of protein, and MERTZ, SEEGER
and SMITH[5] produced evidence that the reactio
prothrombin + Ca'' + thromboplastin = thrombin, is n

but a true chemical combination. The name "thromboplastin" is therefore more accurate. HOWELL also noted in support of the plasma-deficiency theory some experiments by GOVAERTS and GRATIA[6] suggesting that hæmophilic platelets only exhibit exceptional stability in hæmophilic plasma, and that in normal plasma they behave normally. In other words, the platelets themselves are normal.

This theory, though satisfactory in many ways, still leaves important points unexplained. How is the plasma thromboplastin brought into action? How is intravascular clotting avoided? Are the platelets denied all part—as LENGGENHAGER[7] has suggested—in the clotting process? In some recently published experiments QUICK[8] attempts to answer these questions. He starts from the observation of BRINKHOUS[9] that in hæmophilic blood prothrombin is only slowly converted to thrombin. and that after such blood has clotted much prothrombin remains in the serum. QUICK uses the consumption of prothrombin, rather than the coagulation-time of the blood, as a measure of the completeness of the first coagulation reaction. He confirms the finding that hardly any prothrombin is consumed in the clotting of hæmophilic blood, whereas in normal blood 80–85% has been converted to thrombin an hour after clotting. But the prothrombin in hæmophilic blood can be converted to thrombin just as readily as that of normal blood if thromboplastin is added. Either normal plasma or thromboplastin prepared from rabbit brain tissue is effective; but of course plasma thromboplastin does not cause clotting in vivo, whereas tissue thromboplastin does. In order to explain this difference, QUICK again explored the rôle of the platelets. An extract of platelets only slightly accelerates the clotting-time of recalcified oxalated plasma. suggesting that the platelet extract provides no significant amount of thromboplastin. Now in a platelet-free plasma conversion of prothrombin to thrombin is very slow; nevertheless such plasma added to hæmophilic plasma will still restore the normal conversion of prothrombin; in other words thromboplastin is still present. If the hæmophilic plasma is freed as far as possible of platelets by rapid centrifuging, then the addition to this plasma of platelet-free normal plasma will not bring about the relatively complete conversion of prothrombin to thrombin. QUICK explains this by saying that the thromboplastin in normal plasma exists in an inactive form, "thromboplastinogen," which is activated by an enzyme released by the platelets on disintegration. He thus restores the platelets to an active part in blood coagulation; and the defect in hæmophilia is that when platelets disintegrate, and liberate their activator, there is insufficient thromboplastinogen in the plasma to allow formation of enough thromboplastin for significant conversion of prothrombin to thrombin. But the state of affairs is not quite so straightforward, for it has repeatedly been noted by direct observation of shed hæmophilic plasma that platelets do not in fact agglutinate or disintegrate properly. QUICK quotes the findings of PINNINGER and PRUNTY[10] that proper agglutination and disintegration of platelets depends on the formation of a minimal amount of thrombin. In normal blood some thrombin is formed when plasma comes into contact with a foreign surface, but this does not happen in hæmophilic blood.

All the newer evidence is thus in favour of the hypothesis that hæmophilia is a congenital deficiency of plasma thromboplastin, and that all the observed consequences—failure of the blood to clot, non-conversion of prothrombin to thrombin, and even the unusual stability of the platelets—can be traced to this deficiency. It is thus clear that in treatment the provision of thromboplastin is the only correct method. This can be done by transfusing with normal blood or plasma, or by giving intravenously the thromboplastin concentrate known as antihæmophilic globulin, and so restoring the plasma to normal, even if only temporarily. A good case can be made out for giving transfusions before any operative measure, such as tooth-extraction. Since thrombin is the main hæmostatic agent, it is a reasonable contention of QUICK's that the measure of conversion of prothrombin to thrombin gives a better estimate of the likelihood of bleeding than does the simple coagulation-time. For local use thrombin preparations are the first choice.

There are still points to be cleared up, such as the mechanism of the clotting of hæmophilic blood without consumption of prothrombin; and more evidence is needed about the interaction of platelets and thrombin. But much progress has been made, and this should be reflected in simplification of the treatment of hæmophilia.

Service Medicine

No army designed for defence can hope to be fully prepared for war. The date of the conflict, its form. its place, and its scope—these determine the army's constitution, and they can only be guessed. But the guess should take full account of past experience.

The testimony of civilian doctors who worked in or with the Services during the war carries weight because they were in a position to judge the effect of the Service setting on the exercise of their skill. In the first of his Croonian lectures to the Royal College of Physicians last week Dr. E. R. BOLAND offered some friendly criticism on these lines. As a consultant with Allied Force Headquarters, C.M.F., he was impressed with the wastage of medical man-power by the maintenance of separate medical departments for each of the Armed Forces. In voicing the claim for a unified medical service, which has been repeatedly made in these columns,[1] BOLAND admitted that each of the Services has particular problems and needs; but these. he holds, could be met through special formations within the main service. Unification is in fact being considered. but he is not sanguine about the outcome; and he urges that at least medical procedure and documentation should be standardised. In war-time each of the Services uses the medical organisation of the others as occasion demands: and those who served will recall the irritation and confusion caused. particularly at hospital level, by differences in procedure between the three Forces. There will be strong support, too, for BOLAND's further recommendation that the head of the medical services, whether at the War Office or in the field, should be granted a higher status, and that control of these services should pass from the Adjutant-General to a separate branch of the General Staff. In pressing for increased opportunities for training and advancement in clinical work, as opposed to administration, he underlined a defect long plain to doctors both in and outside the Services. The clinician's chances of achieving high rank, though greater than formerly, are still too few; and the effect is to impair efficiency. BOLAND finds it significant that on the whole the men who have brought most lustre to the R.A.M.C. are the pathologists and hygienists, for whom the road to promotion is wider than for others. Openings for advancement, however, must be paralleled by opportunities for training,[2] and BOLAND favours the establishment at home and abroad of Service hospitals which would receive both Service and civilian men and women.

Under modern conditions even more important than increased clinical efficiency is preparation of the Regular skeleton to bear the weight of a vast and rapidly growing body in time of war. Besides being strong, this skeleton must be flexible, and the high level of efficiency demanded of its components cannot be achieved without special training which anticipates the strains of war. On mobilisation, almost at a moment's notice the lance-corporal clerk is appointed chief clerk, and the quartermaster-sergeant is commissioned as lieutenant-quartermaster. Everywhere officers and men are assigned duties a step beyond what they would normally consider the limit of their capacity. But war-time expansion does not involve only advancement in a familiar field; for the quartermaster may find himself a registrar administering a hospital, while his Q.M.S. becomes second-in-command of a medical stores. If this transition is to be smooth, and if, as BOLAND hopes, medical man-power is to be saved in war-time by greater employment of non-medical officers, then preparatory experience is essential. In the Army the possibility of war-time expansion is, of course, acknowledged by training officers and others for duty in higher ranks; but the late war showed that senior N.C.O.'s and non-medical officers in the R.A.M.C. had not been versed in the "shadow" posts which they came to occupy with the outbreak of war. Their training, to be effective, calls for boundless prevision, and similar prevision is required for the curtailment of the medical officer's round of clerical work. In war there is no short-term remedy for the shortage of doctors; and in 1939–45 the needs of the civilian population were barely served. BOLAND suggests that with clerical help the Services could have dispensed with at least one in fifteen of their medical officers; and many, with bitter memories of long hours spent with pen in hand, may retort that this estimate is too moderate. However this may be, experience shows that the saving cannot be effected after war has broken out, for then clerks are at a premium. The time to start saving is now, and a possible solution would be recruitment to the Territorial service of more women clerks who could perhaps be tempted by the prospect of free clerical training.

Annotations

CALCIFEROL FOR CHILBLAINS

CALCIFEROL (vitamin D_2) is one of a series of prod formed when ergosterol is irradiated.[1] Windaus et found that the photochemical reactions involved w

$$\text{Ergosterol}\rightarrow\text{Lumisterol}\rightarrow\text{Tachysterol}\rightarrow\text{Calciferol}\rightarrow$$

$$\text{Toxisterol}\begin{cases}\nearrow\text{Suprasterol 1}\\ \searrow\text{Suprasterol 2}\end{cases}$$

Its administration in large doses has had much atten since Dowling and Prosser Thomas[3] in Britain, Charpy[4] in France proved that when thus give usually relieves or cures cutaneous tuberculosis. (the work on tuberculosis had been accepted, it inevitable that other uses for the remedy would be sou and equally inevitable that it would be tried for chilbl

Reviewing an enormous and unsatisfactory literat Winner and Cooper-Willis[5] note that many Contine doctors regard chilblains as manifestations of tube losis—a view not accepted here. They recall Almroth Wright[6] described diminished coagulabilit the blood in chilblain subjects, thus providing the l for the popular treatment with calcium, but Hallam[7] did not confirm Wright's findings and Percival and Stewart[8] showed that in these subj *the blood-calcium level was consistently normal.* T. appears, in fact, to be little scientific justification giving calcium (with or without vitamin D) for prevention or cure of the lesions. Yet many compe doctors aver that they often do good, and it will req something a good deal more weighty than the ob dicta of consultants and scientists to convince these that their clinical findings are erroneous.

Phelan[9] states that Tecoz, Lavril, Pelicier, and ot have successfully used calciferol in the treatment chilblains by giving 15 mg. (600,000 I.U.) in a si dose, and reports that of 14 cases 8 were cured an *improved by the oral or hypodermic administratio* similar doses of the vitamin. In a paper which publish this week Dr. Anning reaches the contr conclusion that calciferol is ineffective. The controve may perhaps continue until we adopt the Ameri expedient of ensuring an equable temperature in houses. Adequate central-heating banishes chilbla and in many parts of Canada and the United St where the weather can be very cold the word "chilblai has almost vanished from the vocabulary.[10]

In large doses calciferol is a dangerous substan and its dangers have been repeatedly *emphasised.*[11 1] Like the sulphonamides, it can be used carelessly w success on many occasions, so that the unwise physic begins to feel "what fools these clever men be"; a then there is an unexpected tragedy. Though ma people can take large doses for short periods witho apparent harm, a few are intolerant from the fi rapidly developing nausea, headache, vomiting, a prostration. Moreover calciferol can cause a quiesc tuberculous focus in the lungs to flare into activity, a its use is contra-indicated in persons with arterial renal disease. When given for chilblains in doses of, s 50,000 I.U. daily for two or three weeks, it does n carry much risk, provided the patient is health

it is probable that no-one who is not suffering from vitamin-D deficiency can take large amounts for several weeks without suffering some degree of temporary or permanent renal damage. Hence it is inadvisable to give a patient a prescription for calciferol and allow him to use it at his own discretion. If he gives himself several courses of treatment during a succession of winters he may require advice for symptoms far more serious than those of chilblains.

A SOCIAL RESEARCH COUNCIL?

LAST Saturday the Association of Scientific Workers met in London to consider a memorandum on the furtherance of the social sciences. Just over a year ago the Clapham Committee, which had been asked "whether additional provision is necessary for research into social and economic questions," recommended[1] the establishment of (1) a standing interdepartmental Economic and Social Research Committee, and (2) a subcommittee of the University Grants Committee to advise and foster the social sciences within the universities. The association agrees with both suggestions, but also favours the proposal made two or three years ago for the formation of an official Social Research Council, comparable with the Medical Research Council and others concerned with the physical and biological sciences. The Clapham Committee turned this proposal down: (1) because the chief needs of the social sciences are the strengthening of staffs and provision for routine research; (2) because at the present stage of the social sciences an official body might promote crystallisation of spurious orthodoxies: and (3) because the best men must not be diverted from active research to the coördination of research. The association does not dispute that staffs are insufficient, but it holds that in the scramble for trained personnel no unofficial body could adjudicate between the claims of Government and other research establishments. It rebuts the Clapham Committee's contention that existing research councils have never assisted, and are not suited to assist, research carried out as a normal routine function. Many sciences, it says, have fallen into spurious orthodoxies, irrespective of control by official bodies, and the key to safety lies in untrammelled discussion among workers. The danger that the best men may be diverted to duties of coördination is overshadowed, in the association's view, by the need to prevent overlap and to fill the most important gaps.

The association thinks that the Clapham Committee greatly underestimated the importance of increasing social research; and it wants to see teams formed to examine the factual background of social problems and to collaborate with the people who have to carry out social policies.

DICOUMAROL IN CORONARY THROMBOSIS

INCREASING evidence of the value of anticoagulant therapy in the treatment of coronary thrombosis is forthcoming from America. A recent report from the Mayo Clinic is based on a series of 50 cases of acute myocardial infarction admitted to hospital within a few days of onset.[2] In 40 cases dicoumarol was used alone, while in the remainder heparin was also given. The plan of dosage was that recommended by Barker et al.,[3] wherein the aim is to keep the prothrombin level between 10% and 30% of normal. This was achieved by giving 300 mg. of dicoumarol on the first day, and 30 mg. on the second. On each succeeding day that the prothrombin level was greater than 20% of normal 200 mg. was given in a single dose. If the proth level was less than 20% of normal, no dicoumarol w given on that particular day. While an immediate anticoagulant effect is obtained with heparin, there is a lag of 36–48 hours with dicoumarol. The only complications encountered were 1 case of spontaneous hæmorrhage into the knee-joint, which cleared completely, and 1 mild epistaxis; and microscopic hæmaturia was noted in 1 case. The importance of daily estimations of the prothrombin-time is indicated by the finding that in 12 cases the prothrombin level fell to less than 10%, and in 6 of these the intravenous administration of menadione bisulphite was necessary, while in 6 cases the level rose to above 30% for a few days and during this time a second myocardial infarct occurred in one of the patients.

In assessing the results of treatment a series from the same clinic reported by Nay and Barnes[4] was used as a control: of 100 consecutive cases of acute myocardial infarction, in which anticoagulant therapy was not attempted, thrombo-embolic complications ensued in 37%. In contrast to this, in Parker and Barker's 50 cases, treated with anticoagulants, there were only 2 instances of secondary thrombo-embolic complications. Even more interesting is the observation that in the 2 cases that came to necropsy neither pulmonary emboli nor mural cardiac thrombi were present, whereas pulmonary emboli were found in 5, and mural thrombi in 7, of the 11 cases which came to necropsy in the control series. The mortality-rate was not appreciably different in the two series: 10% in the patients receiving anticoagulant therapy and 13% in the control series. The Mayo Clinic report supports the impression from earlier accounts that dicoumarol is useful in the treatment of myocardial infarction.

THE NATIONAL HEARING-AID

IN response to a request by the Ministry of Health, the Medical Research Council appointed, at the beginning of 1944, a committee on electro-acoustics[5] to design a single type of electrically operated hearing-aid, and to determine specifications for pure-tone audiometers. The committee's design for an aid has already been approved by the Ministry of Health; and under the National Health Service this is to be issued free of charge to those found, after examination at special centres, to be in need of it.

In a report published this week,[6] the committee describe the investigations which preceded their choice of prototypes. Intelligibility for speech was regarded as the real measure of success; and theoretical consideration indicated that maximum speech intelligibility need not necessarily result from matching the amplification provided by the aid to the hearing loss of the user. This view was confirmed by practical work at Manchester University and at the National Hospital, Queen Square, London; and it was concluded that, while effective amplification must be provided for all sounds within the $3^{1}/_{2}$-octave range needed for good reproduction of speech, this amplification should increase smoothly with increasing pitch over the lower part of the range, and then either continue to increase at a slower rate or remain constant for the middle and higher-pitched sounds. Piezo-electric microphones were considered to be the most suitable; and a crystal microphone with a metal diaphragm was recommended as being stable under varying atmospheric conditions and as giving the required performance. Small crystal insert receivers are given a word of special commendation, but the committee's aid is designed for both this type and the earcap type. The receiver with a flat earcap advocated in the report is a modification of a miniature unit developed originally for the Fighting Forces; it weighs about an ounce. The battery replacement cost, according to the report, is about 1·1*d.* per hour of actual use with the external receiver type of aid; while with the insert receiver aid the running cost is about 0·6*d.* per hour.

FUMIGATION WITH METHYL BROMIDE

METHYL bromide is mainly used as a refrigerant, as a fire-extinguisher, and as a methylating agent. Recently it has become popular as a fumigant of ships, warehouses, and other premises to control insect pests, and in this connexion fatalities and poisonings have been reported. The chemical being highly toxic to human beings as well as to insects, the Home Office has issued a useful pamphlet[1] on the risks and precautionary measures.

Methyl bromide boils at a low temperature (4·5°C) and it is therefore usually distributed under slight pressure in cylinders containing the liquid, contact with which may cause severe blistering. Clothing contaminated with the liquid should instantly be removed because a high concentration of gas can arise from it. The gas is heavier than air and has greater powers of penetration through walls and sealing material than other common fumigants such as hydrogen cyanide or ethylene oxide. Deaths have resulted both from exposure to high concentrations of the gas and also from continued exposure to low concentrations. The gas is insidious because it has only a faint odour and also because the symptoms after exposure may be delayed for a day or more. The symptoms of poisoning are mainly referable to the nervous system and include headache, dizziness, diplopia, vomiting, and lethargy, with later convulsions and collapse.

The precautions taken should be at least as rigid as those taken when HCN is used, and it is recommended that a pungent lacrimatory gas such as chloropicrin (5%) should be added to methyl bromide so that its presence in the air can easily be detected.

In addition, all apparatus used for the delivery of methyl bromide gas into rooms should be tested before being used in practical operations. The halide detector lamp is recommended for detecting low concentrations of methyl bromide in the atmosphere. These lamps vary in sensitivity to the gas, some types probably not being sensitive enough to detect 17 parts per million of methyl bromide, the figure given as the upper limit of safe concentration. Advice on suitable types can be obtained from the director of the Pest Infestation Laboratory at Slough. It is desirable that the people carrying out fumigation operations should be given practical demonstrations of the performance of the lamps in known concentrations of methyl bromide. The lamps should be used to detect leaks at the time of fumigation, during the exposure period, and before a clearance certificate is issued.

Each operator or other person entering the space under fumigation must be provided with a protective apparatus of proved efficiency against methyl bromide. In high concentrations of the gas a self-contained (oxygen-generating) or a positive-pressure air-breathing apparatus is necessary, but in low concentrations canister respirators of an appropriate type may be used.

Before fumigation, rooms and other spaces should be sealed with an impervious material which should be of an even higher standard than for fumigations by HCN or ethylene oxide. All rooms, compartments, and all ways with walls common to those of the area to fumigated should be evacuated, and warning noti should be affixed. Fumigation staffs should consist of least two persons, and one of them at least should be attendance throughout the fumigation and airing peri Both persons should have adequate colour-vision a should be trained in the use of protective and detec apparatus and in first-aid. The dose of methyl brom should be injected from cylinders placed outside fumigation area. Airing should be conducted and c cluded before the entry of any person other than operators, who should work in pairs and wear th respirators until tests show that the concentration of is a safe one. At this stage a preliminary certificate clearance is to be issued and the fumigated area clo again for a period to guard against the risk of danger quantities of gas being subsequently evolved fr absorbent material. A final certificate of cleara should not be given until thorough tests have been ma Ships should never be fumigated until all persons h been taken off, and special care should be taken to the air in the holds before a clearance certificate is issu

TELEVISION IN SURGICAL OPERATIONS

LAST February surgical operations were televi for the first time at the Johns Hopkins Hospital, Ba more.[1] One camera was fixed 4½ ft. above the operati table, and the image was so sharp that the numbers a dollar bill placed on the table could be clearly read the projection screens. A second camera was instal in the gallery to give a general view of the theat and the surgeon provided a running commentary throu a microphone. The experiment is said to have prov conclusively that demonstration of operations to group of more than three or four is best effected television, even though, for the moment, reproduct is only in black-and-white.

BRITAIN'S HEALTH

THE results of the medical examination of men a women called to the colours in 1939–46 are summaris in a report from the Ministry of Labour and Natio Service.[2] It will be remembered that grades I and were deemed fit for military service, while grades and IV were not. Grade IIa consisted of those w though fit for service, were handicapped by defects visual acuity or by deformity of the feet. Of t 3,240,906 youths under 21, 91% fell into grades I and and 9% into grades III and IV; and of the age-gro 21–25 (1,085,908 men) 85% were fit and 15% un At ages 26–35 (2,045,480 men) the percentages we 79 and 21, and at 36–45 (805,480 men) they were and 35. One should be careful in using these figures a basis for conclusions about the health of the count as a whole, for the scale is heavily weighted at t younger end, where one would expect to find the majori in good health. It is perhaps encouraging, however, th of the relatively few men over the age of 36 the proporti adjudged fit for service was as high as 65%.

Women examined numbered 550,486—less than tenth of the total of men. They were volunteers the sense that they preferred joining the Forces entering industry, and as might therefore be expect they had a rather better health bill than the me though the difference in the proportions accepted a those refused was not great. Among the men e trouble and foot trouble were about equally prevalen but in the women deformities of the feet were not nearly five times as often as defects in visual acuity.

THAT COLD VIRUS AGAIN

The common-cold virus, against which hostilities were for some years suspended, is now the object of a determined search by several groups of laboratory workers in different countries. At Harvard Hospital, Salisbury, the scientific staff of the Medical Research Council is making investigations with the aid of human volunteers.[1] Another group of workers, this time in the University of Texas, has recently recorded observations likewise based on that susceptible animal—the human volunteer. Pollard and Caplovitz[2] inoculated nasal washings from several cases of common cold into the chorio-allantoic cavity of 7-day-old developing chick embryos and passaged the allantoic fluids at 4-day intervals in further embryos by the same route. Bacterial growth was checked by addition of penicillin to the garglings, and the allantoic fluids were tested periodically by intranasal inoculation into human volunteers. The first "strain" gave negative results with materials from the [illegible] passage, the second was infectious for 2 passages but gave mild or negative reactions with 3rd or later passages, and the third "strain" (Spill) induced coryza-like symptoms after 9, 11, and 12 consecutive chick passages. The authors noted that the later passages of this strain induced milder symptoms than the earlier ones: indeed the reactions recorded with 11th and 12th passage material seemed to have scarcely any resemblance to the common cold, though five of the six individuals inoculated with material of the 9th passage might claim that their symptoms of stuffy nose, sneezing, and nasal discharge were equivalent to the natural disease. This part of the report seems convincing enough, though the absence of control volunteers makes the significance of the conclusions uncertain. We are next told, however, that six volunteers were inoculated intranasally with allantoic fluid of the Spill strain in its 9th chick passage, and that five developed colds. These five, together with five new volunteers, were inoculated subcutaneously, at weekly intervals, with two doses of infectious allantoic fluid of the same strain; and one week after the second inoculation they and two control uninoculated subjects received an "immunity test" by the intranasal inoculation of a Seitz-filtered pool of nasal washings from naturally acquired cases of common cold. Only the two "controls" developed symptoms.

Pollard and Caplovitz rightly refrain from commenting on their observations or from making any deductions; for an experiment as important as this might be must certainly be supported by better evidence before it can be accepted at its face value. No virus worker would place much reliance on an observation based on results in ten immunised animals compared with those in two controls. Moreover, the material used for the immunity test was a Seitz filtrate, though the previous cultivation work was based on unfiltered garglings. Finally, of the two control subjects, only one had symptoms severe enough to be classed as a cold for more than twenty-four hours. Much as one would like to welcome these experiments as promising better times in the prevention of the common cold, it cannot be said that they do more than indicate a repetition with more stringent controls. Perhaps it would be as well to add: "Over to you, Salisbury!"

MEETING THE MINISTER

On Dec. 2 and 3 the Negotiating Committee will meet the Minister of Health and hear his response to the argued case they have placed before him. The profession has not yet been informed of the arguments advanced on its behalf, though Dr. Dain has reiterated his opinion that an amending Act is necessary. In difficult circumstances we trust that both sides will nevertheless aim at a reconciliation of views, enabling doctors to enter the service with a degree of good will which has not yet been encouraged to develop.

To

SIR CHARLES SHERRINGTON, O.M.

On his 90th birthday, November 27, 1947

Man shapes the patterns of his mind
As models of the world without,
But to himself he long was blind
And found no answer to his doubt.

You first within the brain discerned
The meaning of its ordered ways,
And man of his own nature learned
To thread the labyrinthine maze.

Poet, you saw the vibrant nerves
Subdued to metrical control,
By which each one in rhythm serves
The guiding purpose of the whole.

These lines a homelier homage bring
Than all the laurels time has brought—
A wish as birthday offering
From world-wide children of your thought.

May age, which clouds the body's eye,
Still leave undimmed the inward sight
That reads life's secret poetry
With timeless wonder and delight!

W. RUSSELL BRAIN

GERIATRIC REHABILITATION *

L. Z. Cosin
F.R.C.S.
MEDICAL SUPERINTENDENT, ORSETT LODGE HOSPITAL,
ESSEX COUNTY COUNCIL

Nurses to attend the aged sick are very scarce, and likely to remain so. It therefore behoves us to diminish the number of aged patients needing much nursing care. This can be achieved by geriatric rehabilitation.

For many patients over sixty years of age progressive deterioration is inevitable, but others may be expected to improve—rapidly or slowly. With an active approach to the problem more and more can receive treatment in bed preparatory to the restoration of assisted or unassisted ambulation. By including this method of treatment at Orsett Lodge Hospital during a recent two-year period, we found that of 780 patients over the age of sixty 45% were rehabilitated, while 35% died and only 10% remained bedfast after six months. (Transfers and more recent admissions account for the remainder.)

AIMS AND METHODS

During the late war we saw how the group encouragement provided in rehabilitation units of the Armed Forces and industry accelerated individual recovery. In these units there were facilities for occupational therapy, physiotherapy, and remedial exercises, with a cheerful and happy environment. This solution suggests that every patient of whatever age and disease needs a hopeful environment for his well-being or recovery; without it convalescence is delayed or deferred indefinitely.

The chief factor in geriatric rehabilitation is the visible improvement of other patients similarly incapacitated, while efficient medical and surgical care are very important subsidiaries. The rehabilitation of our aged patients must begin on admission to hospital, so that the physical and mental deterioration induced by long-continued recumbency does not take place. Tacit acceptance of a poor prognosis—not always accurate—has been responsible for many avoidable deaths from pulmonary embolism in the bedfast.

The aim of geriatric rehabilitation is to restore the maximum degree of painless movement by means of active physiotherapy and remedial exercises, resulting in the maximum of personal independence; we can no longer be satisfied with merely removing pain. If the patient reaches a stage of weight-bearing, assisted or unassisted, so much the better. Utilising simple physiotherapy for a sufficiently long period the proportion of patients who are bedfast can be dramatically reduced. No longer do we label our patients irremediable, incurable, chronic, or senile; instead we make a prognosis based both on diagnosis and on an assessment of the particular person's physical capacities. We recognise that deterioration inevitably accompanies certain irremediable diseases, and that a time must come when the patient will have to remain in bed throughout the 24 hours; but it is surprising how long this point can be postponed. Many patients with advanced malignant disease are happier and complain less of pain when encouraged to get out of bed for a part of each day to help themselves. With few exceptions, in which I include the final inevitable deterioration, the inability of a permanently bedfast patient to feed and generally look after himself is to be regarded as a medical reproach.

FOUR CATEGORIES

Using this method we can recognise that most aged patients fall into certain broad categories.

1. Those patients who cannot provide their own feec and residential arrangements but are otherwise fully con tent to attend to their own needs. They feed themsel dress themselves, and help about the ward. They req no night attention, are continent, and are capable completing light occupational tasks.

2. The frail ambulant who is in need of increased per of rest but can usually cope for himself. (I am adop the provocative attitude of including among these a l proportion of cases of senile dementia and cerebral arte sclerosis; for the criterion of bedfastness should be a suffic physical disability—a condition not obvious in most of t patients.)

These two categories need minimal nursing supervi and extra physical help, for which ward orderlies car employed. Many of those in the first group should no in an institution at all if they could be provided suitable homes.

3. The physically disabled bedfast patient who fe himself, generally looks after himself, and may be cont This class of patient does not make a very heavy call u our nursing service, and we should aim at reabling bedfast patients into this group.

4. The physically disabled permanently bedfast pat who needs every nursing care and attention. In my opi the number in this category, swollen by previous med neglect, should and could be much reduced.

A good medical, surgical, and nursing service al will not reduce the proportion of bedfast patients t minimum unless it embodies the principle of geria rehabilitation. In these days of rapid social change revolt against recumbency must be made successful.

DYNAMICS OF THE CEREBROSPINAL FLU

In a Honyman Gillespie lecture in Edinburgh Nov. 13, Dr. E. A. Carmichael (London) said that original conception of Munro and Kelly of the cran vertebral system as a closed and rigid container h had to be modified in the light of the observed fluct tions in pressure of the cerebrospinal fluid (C.S. Dr. Carmichael and his associates had thought it necess to examine the parts played by the various elastic possibly elastic structures—the arteries, veins, and cap laries, and the meninges—in allowing fluctuations pressure.

Manometric observations were made, mainly on su jects in the erect posture. In most the pressure in t lumbar sac was equal to the distance between the nee and the cisterna magna. Jugular compression did n affect the increase in the lumbar pressure on chan *from recumbent to erect posture.* Thus distension *cranial veins is not itself the factor producing the lumb* pressure in the erect position. *Abdominal compressi* increases the lumbar fluid-pressure in the recumbe subject, but if the subject is raised to the erect postu abdominal compression does not cause further increa The lumbar fluid-pressure appears to reflect the pressu in the lumbar veins. In a patient with a spinal tumo in the lower cervical region which caused comple subarachnoid block, abdominal compression with t subject in the recumbent posture raised the pressu in the lumbar sac to the level of the cistern—i.e., abo the level of the block—and the same change was foun in the erect posture. In other words the patient reacte in the same way as the normal subject. The hypothes that the rise in lumbar pressure in the erect posture associated with dural collapse in the cervical region an distension in the lumbar region was thus refuted; t rise is rather to be attributed to change in pressure the lumbar veins.

A series of studies was made of the spontaneou fluctuations in intracranial pressure in patients wit craniotomy openings. Pressure fluctuations take plac with respiration; little change is recorded durin inspiration, but towards the end of expiration intracrani pressure first rises and then falls. With the subject i bent posture jugular and arm venous pressures during deep inspiration, but in the erect posture the jugular venous pressure does not vary even with deep respiration, and it is evident that variations in intrathoracic pressure during respiration in the erect subject are not transmitted back to the intracranial veins and are not the cause of the fluctuations in intracranial pressure.

---

* Read before the International Conference of Physicians in London, September, 1947.

In the erect posture both intraventricular pressure and cisternal pressure show a rise during deep inspiration, followed by a pronounced and prolonged fall with expiration. It can be shown that, when a spinal tumour wholly blocks communication between the cistern and the lumbar sac, the respiratory fluctuations in the pressures in these two parts are in opposite directions and must be due to different mechanisms. The changes in the lumbar sac appeared to be in response to pressure changes in the abdominal and lumbar veins, but the pressure changes in the cistern could not be related to changes in intracranial venous pressure. During deep inspiration the systolic arterial pressure rises, and it then falls during expiration. Similarly and at the same time, the cisternal pressure rises and falls. If the subject is agitated by the posing of a difficult arithmetical problem the systolic blood-pressure and the cisternal pressure rise. It was shown that these changes are not due to vasoconstriction or vasodilatation of the cerebral vessels. Furthermore, changes in blood oxygen and carbon-dioxide content, although altering C.S.F. pressure, do not do so rapidly enough to be involved in the fluctuations associated with respiration.

Dr. Carmichael concluded that with the subject in the erect position the fluctuations in the cisternal fluid pressure are due to fluctuations in arterial blood-pressure; but fluctuations in pressure in the lumbar sac are due to changes in venous pressure as influenced by respiration. He contended that the dura is not an elastic structure and that the rise in lumbar pressure with the assumption of the erect posture is not due to cervical dural collapse and lumbar dural distension.

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

THE 172nd session opened last Tuesday with an address from the president, Sir HERBERT EASON. He spoke with regret of the death of three former members of the council: Dr. Cecil Wall, Sir Norman Bennett, and Mr. J. A. Woods. The King's *Birthday Honours* list in June included the names of Prof. J. A. Gunn and Dr. Wilfred Fish, who were appointed C.B.E. Professor Gunn, as an original member since 1928, and chairman since 1939, of the British Pharmacopœia Commission, has long been associated with the council. Dr. Fish has been a member since 1942. The president also congratulated Mr. J. J. Robertson, M.P., a Crown nominee to the council, on his appointment as joint parliamentary under-secretary to the Secretary of State for Scotland. He introduced Mr. C. P. Harvey as legal assessor at the new session.

The President has received from the Home Office a letter calling attention to the number of thefts of dangerous drugs and other poisons from cars left unattended by doctors. The Home Office has pointed out that time would be saved and the public safety increased if all doctors would remove poisons from their cars when unattended, or alternatively would lock their cars.

The President regretted that owing to pressure of other business there is no certain prospect of a draft Bill amending the Medical Acts being considered during the present Parliamentary session. "The short draft Bill submitted by the Council to the Government included not only important provisions based on the recommendations of the Goodenough Committee, but also provisions giving practitioners a right of appeal to the Courts against penal erasure from the Medical Register; giving the Council statutory power, which they do not at present possess, to restore the names of practitioners to the Register after penal erasure; enabling the Council to take evidence on oath and to compel the attendances of witnesses by subpœna; and enlarging the direct representation of the profession on the Council. The enactment of such provisions as these would, I believe, commend itself alike to the profession and to the public."

The council then proceeded to the consideration of other business.

LONDON'S VOLUNTARY HOSPITALS

THE practical interest of the public in the voluntary hospitals of London is again well demonstrated in the Annual Statistical Summary for 1946 just published by King Edward's Hospital Fund for London. The total maintenance income (including all free legacies) of the 161 hospitals reached a record figure of £7,360,000. In addition, £195,000 was given for endowment, and £287,000 for building and equipment, making a grand total of £7,842,000—£363,000 more than in 1945 and £2,117,000 more than in 1938, the last complete pre-war year. Income from subscriptions and donations rose by £91,000 to £1,364,000 (1938, £1,091,000): patients' contributions by £224,000 to £1,343,000 (1938, £1,021,000); and contributory schemes by £49,000 to £961,000 (1938, £689,000). Legacies produced £551,000, compared with £676,000 in 1945 and £595,000 in 1938.

Ordinary income amounted to £6,809,000, which was obtained from the following sources: public authorities (25·7%); subscriptions and donations (20%); contributory schemes (14·1%); investment property (10·9%); ordinary patients (9·9%); pay patients (9·8%); central funds (5·2%); fees, &c. (4·4%). Maintenance expenditure amounted to £8,666,000—£2,193,000 more than in 1945 and £3,717,000 more than in 1938—leaving a deficit (after the inclusion of free legacies) of £1,306,000. In 1945 there was a surplus of £410,000, and in 1938 a deficit of £140,000.

A considerable increase over the previous year in the volume of work is recorded. The number of new inpatients rose from 237,000 in 1945 to 266,000 in 1946 (1938, 308,000), and the average number of beds occupied daily from 12,881 to 13,713 (1938, 16,211). New outpatients totalled 1,858,000, compared with 1,635,000 in 1945 and 2,042,000 in 1938, and outpatient attendances 8,925,000, compared with 7,872,000 in 1945 and 10,343,000 in 1938. The summary reflects the enormous increase in the cost of hospital service. In 1938 the average cost of a bed was £233 per annum: in 1946 it was £490, an increase of 110·3%. The average cost per 1000 outpatient attendances in 1938 was £110: in 1946 it was £209, an increase of 90%.

SHORT FORM OF BIRTH CERTIFICATE

A NEW and short form of birth certificate, showing only name and surname, sex, date of birth, and (where possible) place of birth, will be obtainable at a cost of 6*d*. from Monday, Dec. 15. In the case of births registered in England and Wales application may be made to the superintendent registrar of the district in which the birth took place, or to the General Register Office, Somerset House, London, W.C.2. A short certificate may also be obtained from the local registrar at the time of registration of the birth. Where births have been registered abroad and entered in Army, Air Force, Consular, or Marine records deposited with the Registrar-General, certificates may be had only from the General Register Office; and this applies also to certificates relating to adopted children.

The effect of the new certificate is to remove the disability imposed on those of illegitimate birth, who have hitherto had to submit the full certificate, with details of parentage, when required to establish the date of their birth.

In England Now

A Running Commentary by Peripatetic Correspondents

NOTHING could have been less peripatetic than your correspondent between 6.30 A.M. and 12.30 P.M. on Thursday last week as he stood immobile with his solar plexus pressed against an iron rail and his other sides compressed by a solid mass of humanity.

I had come, more or less straight, from a decidedly wet celebration at "the local" of my ship's defeat at both soccer and darts by a sister ship, and had arrived at about 12.30 A.M., when things were still quite lively in the Strand and Square. One could sustain life at the coffee-stalls or on chestnuts, tomatoes, grapes, or even ice-cream. Already the kerbs were strewn with forms in every conceivable attitude of uncomfortable sleep. An enterprising merchant was selling bits of sacking at a bob to keep the chill off. I relied on newspaper as an antihæmorrhoidal and antirheumatic, and between rather frequent visits to the station dozed fitfully with my back against a stanchion.

Between 2 A.M. and 5 things were comparatively quiet, but long before dawn there was a mysterious, incessant twittering, and, as the sky paled, flocks of innumerable starlings swept across the Square, from which the pigeons were entirely ousted by the gradually increasing crowds.

At about 6 I took up my stance on the rails. In my immediate neighbourhood were a most voluble Irishwoman, who persistently cajoled the police with sweets, two ladies in heavy furs, another suffering from a thick leather jacket and pediculosis capitis fulminans, and several children with impetigo very contagiosum.

With the ever-increasing pressure came the faintings, fast and furious. Of the two methods of extrication the Compression Method seemed better on the whole than the Elevation. In the former the patient was forcibly squeezed through the seemingly incompressible mass, and, after being bent double under the rails, emerged flushed and breathless. In the latter they were somehow hoisted above the heads of the crowd and rolled by hand to the St. John's men at the perimeter. I imagine their chief concern was the loss of valuables.

In my vicinity at any rate the B.R.C. was conspicuous by its absence, but St. John had never a dull moment and had even to rope in Scouts as stretcher-bearers.

Maybe this pandemic of syncope was partly due to faulty nutrition. Could it possibly have been aggravated by the surprisingly lugubrious music of the Royal Marine band, whose only inspiration was "O, what a beautiful morning!"? Occasionally one had the impression that the diagnosis might have been feigning rather than fainting, so rapid was recovery when a better view seemed probable. Other opportunists were certainly not slow to take advantage of any disturbance of the mass.

But on the whole the temperament was of a warm-hearted, give-and-take character. I saw a tallish man try really hard to comply with the persistent entreaties from the rear to make himself smaller. I, even I, compressed myself to such an extent as almost to suffer the lamentable fate of Judas I.

As to the pageant itself, in the oft-reiterated phrase of some girls behind me, "It was luv-ly—ain't she luv-ly." And was it worth the effort? Yes, a thousand times yes. But what psychological motivation prompted one to the experience or was satisfied thereby 'twould not be easy to say.

* * *

I have just had my first experience of general practice, and the humour and friendliness of my Welsh patients struck me very much. I found there were two predominant reactions to my arrival: the curious majority said, "Let's go and see what he's like; maybe *he'll* cure us," whereas the cautious minority said, "Let's wait till our own doctor comes back." The strongest supporter of class II was the wifey who asked for Dr. X at the surgery and on being told about me announced with feeling, "I'm not seeing *him*"; and neither she did. I was surprised at the range of cases one sees in a short time—medical, surgical, eyes, ears, noses, throats, fevers, sick kids, and the biggest group of all, those up for "sustifickits."

The people appeared to appreciate being chatted with, about this, that, and the others, and if a G.P. had sufficient time I'm sure he would get much interest out of hi patients. There was the lad who, on being asked about hi work, replied, "I don't work, I'm a student." And th old lady, almost totally bedridden for eleven years, wh got some excitement whenever Dr. X's holiday came roun by thinking to herself "I wonder what this year's locu will be like." I felt sorry for the man who had waite patiently for an hour in the crowded surgery when hi wife phoned: "Is my husband there? Send him hom immediately, and tell him to bring the cat with him. So off he went, with the cat still tucked inside his jacke I don't know whether I was to have seen him or the ca And lastly the doctor's small son. He was very worrie about how I was to go on my rounds, for I had no ca of my own. He asked the dispenser, tearfully, with hi slight lisp: "The new doctor ithn't going to uthe my ne thcooter, ith he?"

* * *

For many years I have done what little I could t curb the use of abbreviations by my students. But had no idea how far this pernicious habit had sprea until I encountered Cecily C. Matthews's new *Dictionar of Abbreviations*.

I am still awaiting the reactions of my friends amon the officials of the Royal Society of Medicine (not to b confused with Regimental Sergeant-Major, Royal Schoo of Mines, or Royal Scottish Museum) to the entr "F.R.S.M. Fellow of the Royal Society of Medicine." Fellows of the Royal Society will be interested to lear that their distinguished initials are claimed by "Federa Reserve System (U.S.A.); Friends' Relief Service Fuel Research Station," but they may be somewha disconcerted by the entry "F.R.S. (L.) Fellow of th Royal Society (London)." Their distinguished presiden shares honours with "Performing Right Society; Proportional Representation Society; Protestant Reformation Society." I had always recognised that my M.D was a stock abbreviation in the psychiatric world, but I had never appreciated its many other uses: "Managing Director; Market Day; 'Medicine and Duty'; Memorandum of Deposit; Mess Deck; Message-Dropping (R.A.F.); Metropolitan District (rly.); Metrology Department; Middle Dutch; Military District; Mine Depot (nav.); Monroe Doctrine"! The B.M.'s among us score heavily compared with the mere M.B.'s: "*balneum marinum* (sea-water bath—med.); Beach Master (R.A.F.); *Beata Maria* (Blessed Mary); *Beatæ Memoriæ* (of blessed memory—Lat.); bench mark; bending moment; Bishop and Martyr; breech mechanism; Brigade Major; British Museum; Bronze Medallist; Brotherhood Movement; Burgomaster." Our friends in Tavistock Square are *paired off* with the Bobbin Makers' Association and British Marine Aircraft.

I had never realised what a wonderful collection of letters our dental colleagues could possess, and I give them full marks for modestly abbreviating their L.D.S. R.C.S. Eng. to a mere L.D.S. For length combined with variety, however, they must be prepared to give way to some of the trade-unions. What, for instance, could be better than Z.C.R.G.S.M.W.S.? which I leave you to interpret for yourself.

* * *

These new-fangled terminologies are very confusing to old fogies like ourselves. The other day I asked the resident anæsthetist what he had given the patient. "Seven point five millilitres of soluble thiopentone" was the astounding answer. I suppose he saw I was startled, for he asked me if I didn't approve of the International System of Weights and Measures. "If you mean the metric system, why not say so?" I retorted peevishly. He was horrified—"But, sir, the metre is a hopeless standard of length, it is supposed to be a certain fraction of the circumference of the earth as calculated. . . ." "Oh, all right," I said wearily, "let it go."

It rather looks as if our light literature will read like this in future.

> That night matters came to a head at the inn. Tom, who had drunk not wisely but too well, spied Dave as he sauntered up to the bar. Heaving his 15 stone (95·45 kg.) off his stool, he flung a pint (568 ml.) of liquor into his face with every ounce (28·4 g.) of his strength. Spluttering with rage and beer, Dave grabbed his heavy riding whip and roared: "You scoundrel, I'll thrash you within an inch (2·54 cm.) of your life."

Letters to the Editor

PENICILLIN IN CASES OF CLOSED ORAL SEPSIS

SIR,—In the past, many teeth have been sacrificed on the altar of systemic disease. Though of recent years more balanced judgments have prevailed. I feel that, with the use of penicillin, the pendulum is tending to swing too far in the opposite direction.
